Rate law for elementary reaction

- Law of Mass Action applies:
 - rate of rxn ∞ product of active masses of reactants
 - "active mass" molar concentration raised to power of number of species
- Examples:

•
$$A \rightarrow P + Q$$

$$rate = k_1 [A]^1$$

■
$$A + B \rightarrow C + D$$

rate =
$$k_2 [A]^1 [B]^1$$

■ 2A + B
$$\rightarrow$$
 E + F + G rate = $k_3 [A]^2 [B]^1$

rate =
$$k_3 [A]^2 [B]^1$$

Molecularity of elementary reactions?

• Unimolecular (decay) $A \rightarrow P$

$$-\frac{d[A]}{dt} = k_1[A]$$

• Bimolecular (collision) $A + B \rightarrow P$

$$-\frac{d[A]}{dt} = k_2[A][B]$$

• Termolecular (collision) $A + B + C \rightarrow P$

$$-\frac{d[A]}{dt} = k_3[A][B][C]$$

· No other are feasible! Statistically highly unlikely.

Reversible reactions (small $\Delta_{r}G$)

$$A \stackrel{k_1}{\rightleftharpoons} B$$

 $A \stackrel{K_1}{\rightleftharpoons} B$ Assume first order, elementary rxn in both directions

Rate:
$$-\frac{d[A]}{dt} = k_1[A] - k_{-1}[B]$$

Conservation of Mass: $[A]_0 + [B]_0 = [A] + [B]$

$$[B] = [A]_0 + [B]_0 - [A]$$

$$-\frac{d[A]}{dt} = k_1[A] - k_{-1}([A]_0 + [B]_0 - [A])$$

Integrate:

$$\ln\left(\frac{k_{1}[A]_{t} - k_{-1}([A]_{0} + [B]_{0} - [A]_{t})}{k_{1}[A]_{0} - k_{-1}[B]_{0}}\right) = -(k_{1} + k_{-1})t$$

$$A \rightarrow B$$

 $[A]_0$ $[B]_0$ initial

If
$$[B]_o = 0$$
, so:
 $[A]_o = [A] + [B]$

If
$$[B]_o \neq 0$$
, so:
 $[A]_o + [B]_o = [A] + [B]$

At equilibrium

$$A \stackrel{k_1}{\rightleftharpoons} B \qquad -\frac{d[A]}{dt} = k_1[A] - k_{-1}[B]$$

At equilibrium...
$$-\frac{d[A]}{dt} = 0 \longrightarrow k_1[A]_{eq} = k_{-1}[B]_{eq}$$

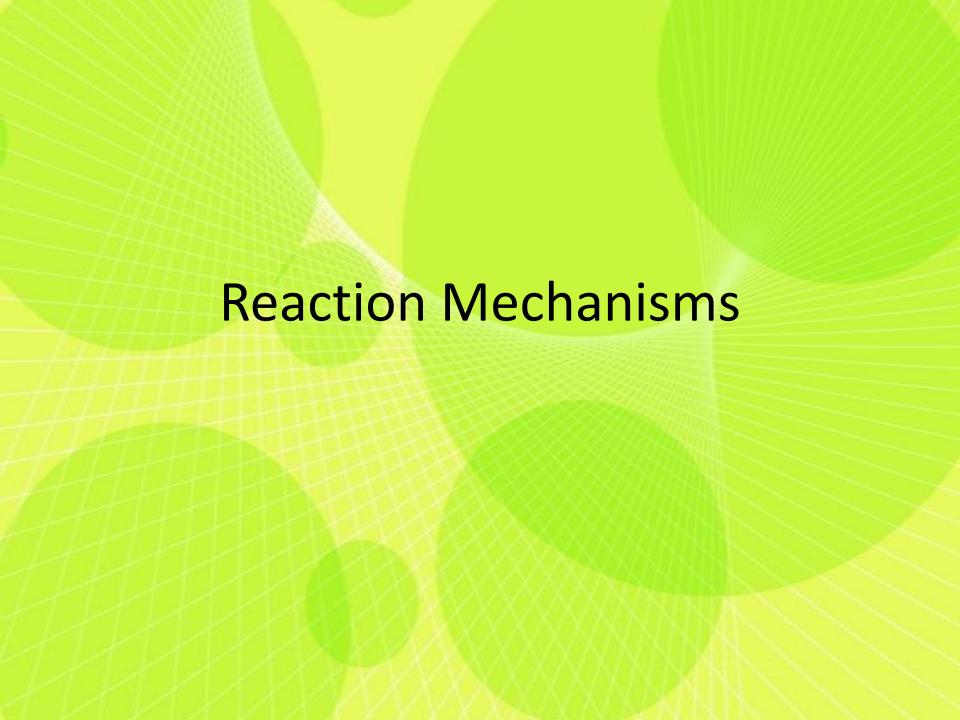

The forward rate equals the reverse at equilibrium.

What is the equilibrium constant for this reaction?

$$K_{eq} = \frac{[B]_{eq}}{[A]_{eq}}$$

In terms of rate constants?

$$K_{eq} = \frac{k_1}{k_{-1}}$$

Always remember....

 One can <u>never prove</u> a reaction mechanism, although evidence may disprove a mechanism.

 Verifying proposed mechanisms requires extensive experimental verification of each proposed step!

Let's examine a reaction ...

$$A \xrightarrow{k_{obs}} P$$

Reaction could progress in multiple ways... How can we distinguish?

Case 1: One elementary step

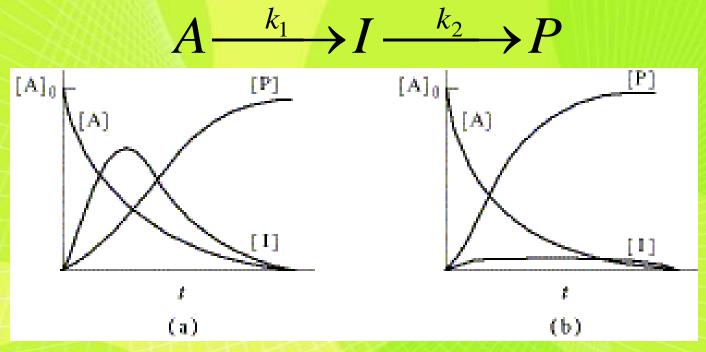

$$A \xrightarrow{k_1} P$$

Case 2: Two step reaction

$$A \xrightarrow{k_1} I$$

$$I \xrightarrow{k_2} P$$

let's focus on the intermediate...

How do k₁ and k₂ relate in case a? in case b?

- (a) I forms quickly but decays slowly... k₁ is fast relative to k₂.
- (b) I builds up to a constant, nearly negligible, concentration until near end of reaction. ... k_1 is slow relative to k_2 .

$$\frac{d[I]}{dt} \approx 0$$
 Steady state approximation... Valid only if k2 > k1.

Rate Laws do not yield unique mechanisms An empirically determined rate law does not imply a unique reaction mechanism!

Consider reaction:
$$2NO(g) + O_2(g) \xrightarrow{k_{obs}} 2NO_2(g)$$

Experimentally, it was determined that the rate is given by:

$$v(t) = k_{obs}[NO]^2[O_2]$$

Researchers proposed two possible mechanisms. They need to determine if one of them is correct.

So how would researchers distinguish between the mechanisms?

Remember the Chain Rxn from CK-6?

$$H_2(g) + Br_2(g) \rightarrow 2HBr(g)$$
 $v(t) = \frac{2k'[H_2][Br_2]^{1/2}}{1 + k''[HBr][Br_2]^{-1}}$

Proposed Mechanism

Initiation:
$$Br_2(g) + M(g) \xrightarrow{k_1} 2Br'(g) + M(g)$$

Propagation:
$$Br^{\cdot}(g) + H_{2}(g) \xrightarrow{k_{2}} HBr(g) + H^{\cdot}(g)$$
$$H^{\cdot}(g) + Br_{2}(g) \xrightarrow{k_{3}} HBr(g) + Br^{\cdot}(g)$$

Inhibition:
$$\longrightarrow HBr(g) + H^{\cdot}(g) \xrightarrow{k_{-2}} Br^{\cdot}(g) + H_2(g)$$

Termination:
$$2Br'(g) + M(g) \xrightarrow{k_{-1}} Br_2(g) + M(g)$$

Elementary Reactions and Mechanism

Elementary reactions are steps of molecular events showing how reactions proceed. This type of description is a mechanism.

The mechanism for the reaction between CO and NO₂ is proposed to be

Step 1
$$NO_2 + NO_2 \rightarrow NO_3 + NO$$
 (an elementary reaction)

Step 2
$$NO_3 + CO \rightarrow NO_2 + CO_2$$
 (an elementary reaction)

Add these two equations led to the overall reaction

$$NO_2 + CO = NO + CO_2$$
 (overall reaction)

A mechanism is a proposal to explain the rate law, and it has to satisfy the rate law. A satisfactory explanation is **not a proof**.

Molecularity of Elementary Reactions The total order of rate law in an elementary reaction is molecularity.

The rate law of elementary reaction is derived from the equation. The order is the number of reacting molecules because they must collide to react.

A molecule decomposes by itself is a unimolecular reaction (step); two molecules collide and react is a bimolecular reaction (step); & three molecules collide and react is a termolecular reaction (step).

$$O_3 \rightarrow O_2 + O$$
 $rate = k [O_3]$
 $NO_2 + NO_2 \rightarrow NO_3 + NO$ $rate = k [NO_2]^2$
 $Br + Br + Ar \rightarrow Br_2 + Ar^*$ $rate = k [Br]^2 [Ar]$

Caution: Derive rate laws this way only for elementary reactions.

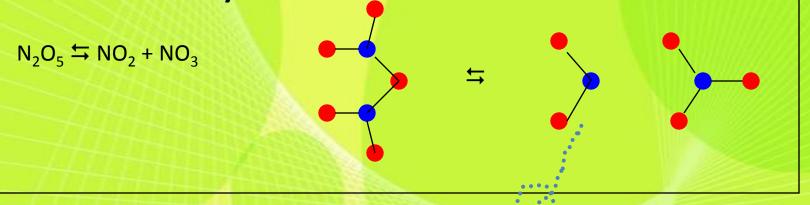

Molecularity of elementary reactions - Example

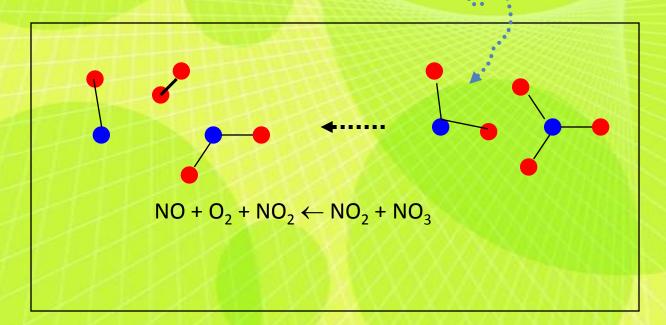

Some elementary reactions for the reaction between CH₄ and Cl₂ are

$$\begin{array}{c} \operatorname{Cl}_2 \rightarrow \ 2 \ \operatorname{Cl} \\ 2 \ \operatorname{Cl} \rightarrow \ \operatorname{Cl}_2 \\ 2 \operatorname{Cl} + \operatorname{CH}_4 \rightarrow \ \operatorname{Cl}_2 + \operatorname{CH}_4 ^* \\ \operatorname{Cl} + \operatorname{CH}_4 \rightarrow \ \operatorname{HCl} + \operatorname{CH}_3 \\ \operatorname{CH}_3 + \operatorname{Cl} \rightarrow \ \operatorname{CH}_3 \operatorname{Cl} \\ \operatorname{CH}_3 + \operatorname{CH}_3 \rightarrow \ \operatorname{CH}_3 \operatorname{-CH}_3 \\ \operatorname{CH}_3 \operatorname{Cl} + \operatorname{Cl} \rightarrow \ \operatorname{HCl} + \operatorname{CH}_2 \operatorname{Cl} \\ \operatorname{CH}_2 \operatorname{Cl} + \operatorname{Cl} \rightarrow \ \operatorname{CH}_2 \operatorname{Cl}_2 \\ ^* * * (\operatorname{more}) \end{array}$$

Write down the rate laws and describe them as uni- bi- or ter-molecular steps yourself, please.

Elementary Reactions are Molecular Events

Rate Laws and Mechanisms

A mechanism is a collection of elementary steps devise to explain the the reaction in view of the observed rate law. You need the skill to derive a rate law from a mechanism, but proposing a mechanism is task after you have learned more chemistry

For the reaction, $2 \text{ NO}_2(g) + F_2(g) \rightarrow 2 \text{ NO}_2F(g)$, the rate law is,

$$rate = k [NO_2] [F_2]$$
.

Can the elementary reaction be the same as the overall reaction?

If they were the same the rate law would have been

rate =
$$k [NO_2]^2 [F_2]$$
,

Therefore, they the overall reaction is not an elementary reaction. Its mechanism is proposed next.

Rate-determining Step in a Mechanism The rate determining step is the slowest elementary step in a mechanism, and the rate

The rate determining step is the slowest elementary step in a mechanism, and the rate law for this step is the rate law for the overall reaction.

The (determined) rate law is, $rate = k [NO_2] [F_2]$, for the reaction, $2 NO_2 (g) + F_2 (g) \rightarrow 2 NO_2 F (g)$, and a two-step mechanism is proposed:

i
$$NO_2(g) + F_2(g) \rightarrow NO_2F(g) + F(g)$$

ii $NO_2(g) + F(g) \rightarrow NO_2F(g)$

Which is the rate determining step?

Answer:

The rate for step i is rate = k [NO₂] [F₂], which is the rate law, this suggests that step i is the rate-determining or the s-l-o-w step.

Explain rate determining step in a mechanism and use it to derive the rate law.

Deriving a rate law from a mechanism - 3

The decomposition of N₂O₅ follows the mechanism:

1
$$N_2O_5 \leftrightarrows NO_2 + NO_3$$

$$2 \qquad NO_2 + NO_3 - k_2 \rightarrow NO + O_2 + NO_2$$

$$3 \qquad NO_3 + NO - k_3 \rightarrow NO_2 + NO_2$$

Derive the rate law.

fast equilibrium slow fast

Solution:

The slow step determines the rate,

rate =
$$k_2$$
 [NO₂] [NO₃]

From 1, we have

$$[NO_2][NO_3]$$
----= $[N_2O_5]$

Thus, rate = $K k_2 [N_2 O_5]$

NO₂ & NO₃ are intermediate

K, equilibrium constant K differ from *k*

Deriving a Rate Law From a Mechanism - 0

The decomposition of H_2O_2 in the presence of I⁻ follow this mechanism,

i
$$H_2O_2 + I^- - k_1 \rightarrow H_2O + IO^-$$
 slow ii $H_2O_2 + IO^- - k_2 \rightarrow H_2O + O_2 + I^-$ fast

What is the rate law?

Energy

Solve the problem

Deriving a rate law from a mechanism - 1

The decomposition of H₂O₂ in the presence of I⁻ follow this mechanism,

i
$$H_2O_2 + I^- - k_1 \rightarrow H_2O + IO^-$$
 slow
ii $H_2O_2 + IO^- - k_2 \rightarrow H_2O + O_2 + I^-$ fast

What is the rate law?

Solution

The slow step determines the rate, and the rate law is:

rate =
$$k1 [H_2O_2] [I^-]$$

Since both $[H_2O_2]$ and $[I^-]$ are measurable in the system, this is the rate law.

Deriving a rate law from a mechanism - 2 Derive the rate law for the reaction, H₂ + Br₂ = 2 HBr,

from the proposed mechanism:

i
$$Br_2 \leftrightarrows 2 Br$$

ii $H_2 + Br - k_2 \rightarrow HBr + H$
ii $H + Br - k_3 \rightarrow HBr$

Solution:

and

The fast equilibrium condition simply says that

$$k_1 [Br_2] = k_{-1} [Br]^2$$

 $[Br] = (k_1/k_{-1} [Br_2])^{\frac{1}{2}}$

The slow step determines the rate law,

rate =
$$k_2$$
 [H₂] [Br]
= k_2 [H₂] $(k_1/k_{-1}$ [Br₂])^{1/2}
= k [H₂] [Br₂] ^{1/2};

total order 1.5

fast equilibrium (k_1, k_{-1}) slow fast explain

Br is an intermediate

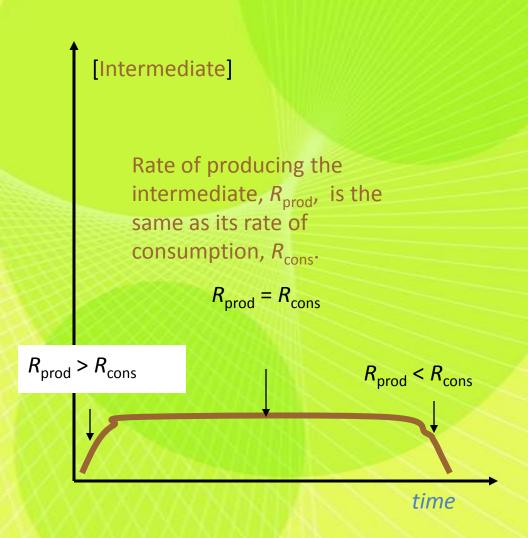

$$k = k_2 (k_1/k_{-1})^{1/2} \text{ M}^{-1/2} \text{ s}^{-1}$$

Deriving rate laws from mechanisms — steady-state approximation

The steady-state approximation is a general method for deriving rate laws when the relative speed cannot be identified.

It is based on the assumption that the concentration of the intermediate is constant.

Be able to apply the steady-state approximation to derive rate laws

Let's assume the mechanism for the reaction.

$$H_2 + I_2 \rightarrow 2 HI$$

as follows.

Step (1)
$$I_2 - k_1 \rightarrow 2I$$

Step (-1) 2 I
$$-k_{-1} \rightarrow I_2$$

Step (2)
$$H_2 + 2I - k_2 \rightarrow 2HI$$

Derive the rate law.

Derivation:

rate = k_2 [H₂] [I] ² ('cause this step gives products)

but I is an intermediate, this is not a rate law yet.

Since
$$k_1[I_2]$$
 (= rate of producing I)
= $k_{-1}[I]^2 + k_2[H_2][I]^2$ (= rate of consuming I)

:.
$$rate = k_1 k_2 [H_2] [I_2] / \{k_{-1} + k_2 [H_2] \}$$

Steady-state approximation - 2

Steady state

Steady-state approximation - 3

From the previous result:

Discussion:

```
(i) If k_{-1} \ll k_2 [H<sub>2</sub>] then \{k_{-1} + k_2 [H<sub>2</sub>]\} = k_2 [H<sub>2</sub>], then rate = k_1 k_2 [H<sub>2</sub>] [I<sub>2</sub>] / \{k_2 [H<sub>2</sub>]\} = k_1 [I<sub>2</sub>] (pseudo 1st order wrt I<sub>2</sub>) using large concentration of H<sub>2</sub> or step 2 is fast (will meet this condition).
```

```
(ii) If step (2) is slow, then k_2 << k_1, and if [H_2] is not large, we have \{k_{-1} + k_2 [H_2]\} = k_{-1} and rate = k_1 k_2 [H_2] [I_2] / k_1 = k_2 [H_2] [I_2]
```

Steady-state approximation - 4 In an alkaline solution, peroxydisulfate oxidizes sulfite to yield sulfate,

$$S_2O_8^{2-} + SO_3^{2-} + 2OH^- \rightarrow 3SO_4^{2-} + H_2O.$$

The following mechanism has been proposed:

i
$$S_2O_8^{2-} + SO_3^{2-} - k_1 \rightarrow S_2O_7^{2-} + SO_4^{2-}$$

ii
$$S_2O_7^{2-} + H_2O - k_2 \rightarrow 2 SO_4^{2-} + 2 H^+$$

iii
$$H^+ + OH^- - k_3 \rightarrow H_2O$$
 (fast equilibrium to be discussed)

Steady-state approximation follows these steps:

What is or are the intermediates I?

Use which step to give the rate law that may involve [I]?

Express the *rates* of producing and consuming intermediate(s)

Express [I] of intermediate(s) in terms of [Reactants]

Derive the rate law in terms of [Reactants]

Discuss

Catalysis

Energy

A catalyst is a substance that changes the rate of a reaction by lowing the activation energy, E_a . It participates a reaction in forming an intermediate, but is regenerated.

Enzymes are marvelously selective catalysts.

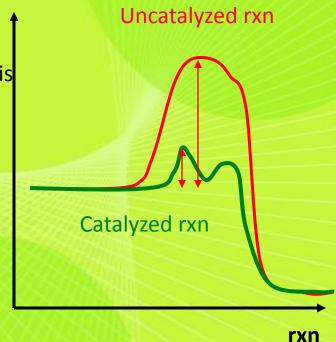

A catalyzed reaction,

$$2 SO2 (g) + O2 \longrightarrow 2 SO3 (g)$$

i
$$2 NO + O_2 \rightarrow 2 NO_2$$

i
$$NO_2 + SO_2 \rightarrow SO_3 + NO$$

(3rd order)

Catalyzed decomposition of ozone

R.J. Plunkett in DuPont discovered carbon fluorine chlorine compounds.

The CFC decomposes in the atmosphere:

$$CFCl_3 \rightarrow CFCl_2 + Cl$$

 $CF_2Cl_3 \rightarrow CF_2Cl + Cl$.

The Cl catalyzes the reaction via the mechanism:

i
$$O_3 + h v \rightarrow O + O_2$$
,
ii $ClO + O \rightarrow Cl + O_2$
iii $O + O_3 \rightarrow O_2 + O_2$.

The net result or reaction is

$$2 O_3 \rightarrow 3 O_2$$

Scientists sound the alarm, and the CFC is banned now.

Homogenous vs. heterogeneous catalysts

A catalyst in the same phase (gases and solutions) as the reactants is a homogeneous catalyst. It effective, but recovery is difficult.

When the catalyst is in a different phase than reactants (and products), the process involve heterogeneous catalysis. Chemisorption, absorption, and adsorption cause reactions to take place via different pathways.

Platinum is often used to catalyze hydrogenation

Catalytic converters reduce CO and NO emission.

Heterogeneous catalysts

Ceryx's vision is to design, produce, and commercialize advanced systems that balance Cost, Performance, Emissions Reduction, and Fuel Penalty to make the economics of pollution control viable.

We explore new ways to look at the air quality challenges faced by industry and search for potential solutions by combining proven technologies with state-of-the-art science.

Catalyzed reactions:

$$CO + O_2 \rightarrow CO_2$$

$$2 NO \rightarrow N_2 + O_2$$

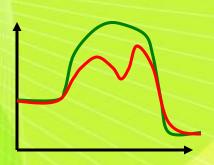

Enzymes – selective catalysts

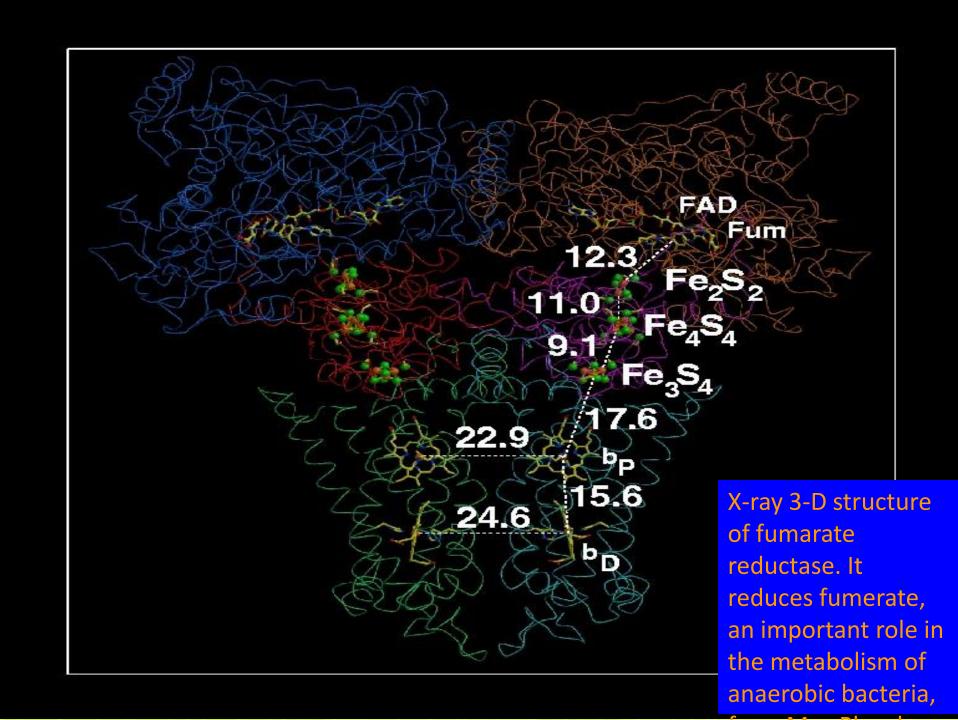

Enzymes are a long protein molecules that fold into balls. They often have a metal coordinated to the O and N sites.

Molecules catalyzed by enzymes are called **substrates**. They are held by various sites (together called the **active site**) of the enzyme molecules and just before and during the reaction. After having reacted, the products P_1 & P_2 are released.

$$E_{nzyme} + S_{ubstrate} \rightarrow ES$$
 (activated complex)
 $ES \rightarrow P_1 + P_2 + E$

Enzymes are biological catalysts for biological systems.

Chemical Kinetics - Summary

Explain how the various factors affect reaction rates.

Define reaction rates, average rates, initial rates and rate constants. Evaluate rate law from experiments

Properly apply 1st and 2nd differential rate laws and integrated rate laws.

Interpret elementary reactions and mechanisms. Derive rate laws from a given mechanism. Apply the steady-state method to derive the rate law of a given mechanism, and discuss the results.

Explain the action of catalysts in terms of chemistry and in terms of energy of activation.
