Editor:
Assoc. Prof. Dr. Mehmet Hasan Eken

Associate Editor:
Dr. Serkan Çankaya

Preface

Welcome to the Tenth Annual Conference of the Asian Academic Accounting Association hosted by Kadir Has University in Istanbul on Novemner 15-18, 2009! This is the first time that this prestigious conference is being held in Turkey. We are delighted to be the hosts for the auspicious tenth year of the conference. The Asian Academic Accounting Association is the premier professional organization for accounting academics across Asia. Its mission is to enhance accounting education and research and to build strong ties with the professional accounting community. The conference typically attracts accounting academics from over thirty countries along with members of the business community from the host country.

This year we received 175 manuscripts from academicians in 42 countries on five continents. 95 of these papers have been selected for presentation at the concurrent sessions, after two blind reviews. An additional 17 manuscripts were selected for the research forum applying the same review procedure. We anticipate 200 registrants, including accounting professionals in Turkey, at the conference.

This conference has been organized by a team of seven academicians. Two members of this team including Dr. Mehmet Hasan Eken, incoming AAAA President and Dr. Serkan Çankaya (both of Kadir Has University) have worked particularly diligently over the past year on organizing this conference. The AAAA appreciates their tremendous contributions in making the conference a great success.

This proceeding book contains 95 manuscripts that have been presented at the conference in various areas of accounting and finance alphabetically listed below. The conference program also lists the manuscripts for the research forum.

1- Accounting Education
2- Auditing
3- Behavioral Issues in Accounting
4- Capital Markets
5- Corporate Finance
5- Corporate Governance
6- Earnings Management
7- Financial Reporting
8- International Accounting
9- Islamic Accounting, Banking and Finance
10- Management Accounting
11- Social and Environmental Accounting
12- Social Responsibility
13- Other Issues in Accounting

Shahrokh M. Saudagaran   Mehmet Hasan Eken
Secretary General   President

Plenary Session - Preparing for a lifelong career in Academia - Shahrokh Saudagaran – University of Washington

Monday, November 16, 2009

9:00 AM – 10.00 AM
Registration

10:00 AM – 11.30 AM
Opening Plenary

M. Hasan Eken –Director of Institute of Social Sciences – Kadir Has University, President-Elect, AAAA

Shahrokh Saudagaran - Dean for the Milgard School of Business - University of Washington, Secretary-General, AAAA

Masum Türker - TÜRMOB

Yücel Yılmaz – Rector of Kadir Has University

Keynote Speaker

Bülent Üstünel – Chairman of Turkish Accounting Standards Board

11:30 AM – 12:00 AM
Refreshment Break

12:00 AM – 13:30 PM
Concurrent Sessions

Session 1.1: Accounting Education   Room 1
Moderator: Lindawati Gani, Universitas Indonesia, Indonesia

Accounting Technicians' Capabilities: the Employer and Student Perspectives
Shirley Carr, (Massey University, New Zealand), Frances Chua (Massey University, New Zealand), Mike Fermor, Universal College of Learning (UCOL), Whanganu, New Zealand

Back to the Basic -- Accounting as Number-crunching Courses
Arief Surya Irawan (Universitas Gadjah Mada, Indonesia), Sony Warsono (Universitas Gadjah Mada, Indonesia), Arif Darmawan (Accounting Division of Accounting Corner, Indonesia), Muhammad Arsyadi Ridha (Accounting Division of Accounting Corner, Indonesia)

Benchmarking the First Year Accounting Unit: Some Evidence from Australia
Nick Sciulli (Victoria University, Australia), Malcolm Smith (Curtin University, Australia), Phil Ross (University of Western Sydney, Australia)

1.2 Behavioral Issues in Accounting   **Room 2**
Moderator: Sidharta Utama, University of Indonesia, Indonesia

Do Analysts' Recommendations Contribute to the IPO Underperformance Puzzle?
Chee-Meng Yap (National University of Singapore, Singapore), Yew-Kee Ho (National University of Singapore, Singapore)

Do digital reporting formats impact decision accuracy and cognitive effort?
Fawzi Laswad (Massey University, New Zealand), Erlane K. Ghani (Universiti Teknologi Mara, Malaysia), Stuart Tooley (Queensland University of Technology, Australia)

Fairness Perceptions and Compliance Behavior: New Zealand Evidence
Natrah Saad (University of Canterbury, New Zealand)

1.3 Earnings Management   **Room 3**
Moderator: Miho Nakamura, Oita University, Japan

Does Investor Protection Affect The Choice Of Earnings Management Methods Through Real Activity Manipulation And Accrual Manipulation? Asian Comparison
Ratna Candra Sari (Gadjah Mada University, Indonesia), Sony Warsono (Gadjah Mada University, Indonesia), Sri Suryaningsum (Gadjah Mada University, Indonesia)

The Effect of Majority Shareholder Ownership on Real Earnings Management: A Korean Perspective
Ho Young Lee (Yonsei University, South Korea), Jai-Min Goh (Yonsei University, South Korea) Lee Jung-Wha (Hanyang University, South Korea)

Related Parties' Transaction and Earnings Management: A Case in Indonesia
Sumiyana (Universitas Gadjah Mada, Indonesia), Rahmat Febrianto (Universitas Andalas, Indonesia)

1.4 Capital Markets **Room 4**

Moderator: Pradyot K. Sen, University of Cinninati, USA

Further Evidence from Emerging Capital Markets that both Firm-Specific and Market-Wide Regime Shifting Behavior Approach Explains Asymmetric Price Reaction
Slamet Sugiri (Universitas Gadjah Mada, Indonesia), Sumiyana (Universitas Gadjah Mada, Indonesia)

Have the economic effect of Japanese corporate merger changed?
Ohashi Yoshitaka (The University of Aizu, Japan), Takahashi Mioko (Takasaki City University of Economics, Japan)

Impact of Quarterly Disclosure on information Asymmetry: Evidence from Tokyo Stock Exchange Firms
Hitoshi Takehara (Waseda University, Japan), Keiichi Kubota (Chuo University, Japan), Kazuyuki Suda (Waseda University, Japan)

1.5 Corporate Governance **Room 5**

Moderator: Yoshikazu Ishinagi, Nagoya University, Japan

Agency Theory and Managerial Ownership: Evidence from Malaysia
Mazlina Mustapha (Universiti Putra Malaysia, Malaysia), Ayoib Che Ahmad (Universiti Utara, Malaysia)

Antecedents of CEO Selection in Malaysian Public Listed Companies
Rokiah Ishak (Universiti Utara Malaysia, Malaysia), Ku Nor Izah Ku Ismail, Shamsul Nahar Abdullah

Board Composition Expertise and Earnings Quality
Hafiza Aishah Hashim (Universiti Malaysia Terengganu, Malaysia), S. Susela Devi (Universiti Malaya, Malaysia), Ferdinand A Gul (The Hong Kong Polytechnic University, Hong Kong)

1.6 Research Forum **Room 6**

Moderator: TBD

13:30 PM – 14:30 PM
Lunch Break

14:30 PM – 16:00 PM
Concurrent Sessions

Session 2.1: Accounting Education   **Room 1**
Moderator: Shirley Carr, Massey University, New Zealand

Data Examining Postings to the Discussion Board in Introductory Accounting
Abdel K Halabi, (University of Witswaterrand,South Africa)

Investigation of Importance Ethics Education in Accounting Curriculum
Saeed Jabbarzade Kangar Lue (IAU of Urmia, Iran), Akbar Pourreza Soltan Ahmadi (IAU of Salmas, Iran)

The Use of Reflective Learning Journals as a Learning and Assessment Method within an Entry Level Tertiary Accounting Paper
Louise MacKenzie (University of Otago, New Zealand), Malcolm Smith (Curtin University, Australia), Phil Ross (University of Western Sydney, Australia)

2.2 Management Accounting   **Room 2**
Moderator: Bülend Terzioğlu, Australian Catholic University, Australia

Production Costs And Cost Management Practices Of Turkish Manufacturing Companies (ici 500): A Descriptive Study
Yusuf Ağ (Bozok University, Turkey), Murat Kocsoy (Bozok University, Turkey)

The Effects of Management Demography on Auditor Choice and Earnings Management: Evidence from China

The Effects of Strategy-Control System Misfits on Firm Performance

Lindawati Gani (Universitas Indonesia, Indonesia), Johnny Jermias (Simon Fraser University, Canada)

2.3 Earnings Management   Room 3
Moderator: Chee Meng Yap, National University of Singapore, Singapore

Reporting Comprehensive income and Managerial Behavior in Japan
Miho Nakamura (Oita University, Japan)

The Effect of Corporate name change on the Earnings Management in KOREA
Soon Suk Yoon (Chonnam National University, South Korea), Min Kyong Park (Chonnam National University, South Korea)

The Effect of Earnings Management through Real Activities on Future Operating Performance (Empirical Evidence from Manufacturing Firms Listed in Indonesia Stock Exchange)
Sylvia Veronica Siregar (University of Indonesia, Indonesia), Rizqa Liaviani Afif (University of Indonesia, Indonesia)

2.4 Capital Markets   Room 4
Moderator: Sudi Apak, Beykent University, Turkey

Life after IPO: Financing and Investing Activities of New Public Listed Firms in Indonesia
Dezie L. Warganegara (BINUS University, Indonesia), Josephine Nicole (BINUS University, Indonesia)

Market Reaction to the Announcement of Related Party Transactions
Sidharta Utama (Fakultas Ekonomi Universitas Indonesia, Indonesia), Cynthia A. Utama (Fakultas Ekonomi Universitas Indonesia, Indonesia), Rafika Yuniasih (Fakultas Ekonomi Universitas Indonesia, Indonesia)

Private Information Arrival at Indonesia Stock Exchange, Reality or Imaginary? U-Shaped Return Variance Curve Verification
Setiyono Mihardjo (Universitas Gadjah Mada, Indonesia), Sumiyana (Universitas Gadjah Mada, Indonesia)

2.5 Corporate Governance   **Room 5**
Moderator: Rokiah Ishak, Universiti Utara Malaysia, Malaysia

Corporate Governance and Performance of the Listed Companies in TSE
Vida Mojtahedzadeh (Al-Zahra University, Iran), Seyed Hossein Alavi Tabari (Al-Zahra University, Iran)

Corporate Governance and Board Performance: Evidence from Public Listed Companies in Malaysia
Hasnah Kamardin (Universiti Utara Malaysia, Malaysia), Hasnah Haron (Universiti Sains Malaysia, Malaysia)

Relationship Between Directors' Bonus and Shareholders' Value: A View from Corporate Governance
Zubaidah Zainal Abidin (Universiti Teknologi MARA), Akhma Adlin Khalid (Telekom Malaysia Berhad)

2.6 Research Forum   **Room 6**
Moderator: TBD

16:00 PM – 16:30 PM
Coffee Break

16:30 PM – 18:00 PM
Concurrent Sessions

Session 3.1: Financial Reporting   **Room 1**
Moderator: Sumiyana, Universitas Gadjah Mada, Indonesia

Risk Relevance of Accounting Variables
Vida Mojtahedzadeh (Al-Zahra University, Iran), Rahele Homayouni Rad (Al-Zahra University, Iran)

Comparison of the Value Relevance between the Purchase and Rental Treatment of Leases

Eiko Sakai (Musashi University, Japan)

M&A goodwill accounting: "Those are my principles, and if you do not like them..."
Humberto R Ribeiro (Bragança Polytechnic Institute, Portugal)

ACCOUNTING TECHNICIANS' CAPABILITIES: THE EMPLOYER AND STUDENT PERSPECTIVES

Shirley Carr, Academic Director, College of Business, Massey University, New Zealand
Frances Chua, Lecturer, School of Accountancy, Massey University, New Zealand
Mike Fermor, Lecturer, Universal College of Learning (UCOL), Whanganui, New Zealand

ABSTRACT

As accountants face pressure from a skills shortage, increasing regulation and a widening range of services to clients, professional bodies are paying more attention to paraprofessionals, the accounting technicians (ATs). This group of paraprofessionals, many of whom are not affiliated to a professional body, has a worldwide presence and is perceived to be an increasingly valuable part of the accounting services supply chain. As such, improving the credentials of this group may be seen as a way of legitimising their role in the provision of accounting services. With a rapidly growing paraprofessional sector, the profession has a responsibility to ensure that AT entry requirements, that is, AT education and training, are relevant and set at an appropriate level. In particular, the competence, skills and integrity of this group need to meet the expectations of the public, employers and the profession.

This paper reports the results of an opinion survey of New Zealand ATs and their employers on the relevance of AT skills, attributes and knowledge in their work environment. The findings suggest that although ATs perform a variety of technical tasks in the workplace, the employers tend to consider an AT's integrity, communication, and problem solving skills to be more important than their technical skills. Further, the ATs found that many of the key skills, attributes and areas of knowledge identified as being important to their work activities, were not adequately covered in their formal education. The findings also suggest that more ATs are electing to complete a degree in accountancy. All these may have implications for the traditional sub-degree diploma route, and the positioning of ATs in the profession.

Keywords: accounting technicians, accounting profession, admission policies, competence

INTRODUCTION

Professions are an integral part of society. The accounting profession, as one of the so-called "elite" professions, is a critical and indispensable element in any economy depending on private capital. Over the years, the accounting profession has attempted to maintain its relevance in light of the rapid changes in the business environment. However, with increasing demands for accounting services, it is facing a skills shortage with paraprofessionals, namely, accounting technicians (ATs), working in supporting roles of accounting services. Some of these paraprofessionals are affiliated to a professional body while others are not.

A growing para-professional sector in accounting raises questions of quality for the profession. In the last few decades, attempts have been made by the UK, Australia and New Zealand professional accounting bodies to legitimise the supporting role of accounting personnel. To ensure that the quality of work of the accounting technicians is acceptable to the employers and does not erode the image of the profession, it is the responsibility of the accounting profession to oversee the entry requirements of this group - whether the entry academic requirements are relevant to the changing environment, and whether their levels of competence, skills and integrity meet the expectations of the public, employers and the profession. The interaction between employers, educators and other members of the profession is complex but important as this can have major impact on educational programmes and professional admission policies. However, very little research has been conducted on this group despite the increasing contribution they make to the business sector and accounting services in particular. In New Zealand, the accounting technician qualification and curriculum have not been validated over the last decade even though an Associate Chartered Accountants (ACA) designation was reintroduced in November 2006. International interest in accounting education has typically focused on the chartered accountancy (CA) level of the profession. In view of this situation, this paper examines what is traditionally considered the accounting paraprofessionals - the accounting technicians in the New Zealand context. More specifically, it aims to survey both ATs and their employers to ascertain whether the current academic requirements for New Zealand ATs meet the needs of their workplace.

The paper is structured as follows. As a backdrop, section one describes the role of the accounting technician by highlighting the differences between professions and paraprofessions in general and in accountancy in particular. Section two reviews the current development of accounting technicians in New Zealand. Section three examines the required skills, attributes

and knowledge of accounting technicians. Section four explains the research design. Section five discusses and analyses the results of the survey before drawing some conclusions in the final section.

THE ROLE OF THE ACCOUNTING TECHNICIAN

The concept of the technician is not new to professions. The accountancy profession has employed personnel in technician type of jobs for many years. The formal recognition of their existence by established professional bodies, however, is a relatively recent development. By legitimizing their existence, the professional bodies have assumed some control over the group, including the type and standard of work they do. In order to understand the different roles between the professional accountant and the accounting technician, it is necessary to examine the different roles and rules of the two groups.

Professions and paraprofessions

Over the years, social scientists such as Abbott (1988), Emmet (1966), Greenwood (1966), Larson (1977) and Moore (1970) have studied the professions and compiled lists of specific observable professional attributes. Although the lists can vary from one scientist to another, the systematised views of professions tend to share some common characteristics as identified by Larson (1977, p.208): professional association, cognitive base, institutionalized training, licensing, work autonomy, colleague "control", and code of ethics. Implicit in these attributes is the notion of a standard of professional performance supported by a sense of integrity, whereby professional members have a fiduciary trust to maintain in carrying out functions valued in the society.

The sociology of the professions also reveals that they are normally characterised by minute division of labour based on technical specialisation - some form of social differentiation or stratification. This division of labour is "organized into a hierarchy of authority, established and enforced by law, and swinging around the dominant authority and responsibility" (Freidson, 1970, p. 76). For instance, the "paramedical" such as nurses and paramedics are part of a division of labour of the medical profession. They are subordinate members of the medical division of labour and are clearly in a markedly different position from the physicians. Even though sometimes they call themselves and are perceived by others as "professions," they are not the equals of physicians since they do not possess the same autonomy of physicians and therefore cannot be classified as the same type of occupation as physicians. In short, they "are

specifically and generically occupations organized around a profession – paraprofessional occupations" (Freidson, 1970, p.76). It can therefore be explained that, paraprofessions, given their proximity to a profession, are encouraged to take on professional attributes and to claim to be a profession. It might also be noted that paraprofessional occupations usually seek professional status by creating many of the same institutions as those which possess professional status. They develop a formal standard curriculum of training, use theory to teach recruits, issue codes of ethics, and are prone to seek support for licensing or registration so as to exercise some control over who is allowed to do their work. This in itself makes a distinct species of occupation or profession, but whatever the claim, they do not stand in the same structural position as the profession on which they model themselves because their autonomy is limited by the dominant profession (Freidson, 1970).

Accounting technicians as supporting personnel

In accounting, this paraprofessional group is represented by the accounting technicians (AT). Here, social differentiation and stratification between the roles of the professional (chartered) accountant and accounting technician is discernible from the definition provided by the International Federation of Accountants (IFAC) Taskforce on the Role of Accounting Technicians (1994):

> [They] differ from the other staff in other forms of accountancy training in that they are specifically trained as support staff; they are almost always working under the supervision and control of accountants; they are skilled in the technique of accountancy and computing as technicians; the most able of them can and do progress, if suitably motivated, to qualify as accountants. They differ from accountants in that they start training younger and without the necessary entry qualifications for an accountancy qualifications; if involved in decision-making at all, they are supervised and deal with less complex and technical financial decisions whilst providing a service to accountants; they produce the financial statements and accounts which are then used and interpreted by accountants according to the rules set by accountants. (p.2)

This elucidation complements an earlier IFAC publication – International Education Guideline 9 (IEG9) (IFAC, 1987b), which states that professional accountants ought to be professionally competent, that is, they must have the required knowledge, the ability to apply that knowledge to practical problems and also have a professional approach to their work. The accounting technician, on the other hand, has the skills at a technical level in specific areas of accounting, without necessarily the knowledge, skills and ability to handle general problems at a professional level. In short, accounting technicians provide ancillary and complementary

services as support to an accountant's wider and more comprehensive role. In this role, they may not be required to have the same levels of understanding and application as that of professional accountants. However, their job certainly involves a higher level of responsibility than does a purely routine clerical job (IFAC, 1987a). They help to increase efficiency by relieving qualified accountants of the routine and detailed tasks so that they can devote more time to tasks that require higher level of expertise.

Undoubtedly these IFAC documents have provided guidance to its member professional bodies in their designation of the accounting technician. For instance, in the UK, accounting technicians are defined as "the second tier of the accountancy profession, responsible for bookkeeping rather than accountancy functions (Evans, 1993, p.56). They work at all levels of finance from accounts clerk to financial controllers in all industries and sectors and in large and small organisations. The Institute of Accounting Technicians in Ireland (IATI) describes its members as "persons who have acquired training, experience and knowledge that will enable them to work at middle management level and to provide support services for senior management (1995, p.2). In Australia, accounting technicians "work in all levels of finance and accounting and fulfil roles from accounts staff to finance or office managers[1]"(AAT Australia, 2008). In New Zealand, accounting technicians are defined as "para-professionals skilled in providing support services for professional accountants and senior management in their organisations" (NZSA, 1995, p.81). The group is sometimes referred to as middle-level accountants who are skilled in the practical aspects of accounting and information systems and are adept at the finance/accounting function such as recording transactions, preparing accounts and statements, providing financial and management information, managing accounting systems, and establishing taxation liabilities, etc. (Franks, 1996, p.60).

Professional affiliations

To protect their own interests and to show commitment to high standards, professionalism, recognition and status befitting accounting paraprofessionals, accounting technicians have organised themselves into professional associations with the support of the established accounting bodies. To date, the largest body of accounting technicians is the Association of Accounting Technicians (AAT) in the UK with over 100,000 members worldwide (AAT Review, 2007). The Association, which is sponsored by the Chartered Institute of Public Finance and

---

[1] These include accounts payable officer/clerk, accounts receivable officer/clerk, payroll officer/clerk, finance manager, finance assistant, assistant accountant, bookkeeper, trainer accountant. Reconciliation officer/clerk.

Accountancy (CIPFA), the Institute of Chartered Accountants in England & Wales (ICAEW), the Chartered Institute of Management Accountants (CIMA), and the Institute of Chartered Accountants of Scotland (ICAS), states that it is committed to developing amongst its members a high standard of competence, and providing professional development opportunities for them in achieving this objective. The members are bound by professional ethics and disciplinary procedures as the basis of maintaining public confidence. Other AT professional bodies such as the Association of Chartered Certified Accountants (ACCA), the Institute of Accounting Technicians in Ireland[2] (IATI), AAT Australia[3] and the AT college of the New Zealand Institute of Chartered Accountants (NZICA) have adopted similar mission and objectives. The statement put forth by the IATI in its website (2008, www.iati.ie/index) can be regarded as a fair representation of the mission of accounting technicians:

> … to serve the interests of our members, our students, the accountancy profession, the business community and the wider public by providing an accounting technician qualification of recognised international standard, by promoting the highest educational, technical and ethical standards, and by providing our members with opportunities for realising their potential and advancing their careers through continuing education and lifelong learning.

the AAT has since 1992 started to recruit members through a competence-based scheme to ensure that the assessment requirements are not restricted to the examination of acquired knowledge but encompass the full range of competences required of accountancy personnel in the workplace. Currently, it offers two basic pathways to the AAT qualification: the National Vocational Qualifications (NVQs)/Scottish Vocational Qualifications (SVQs) which is workplace-based, and the Diploma pathway which involves full or part-time study at a College or training centre in addition to one year's work experience (www.aatglobal.com/Structure.htm# Pathway/, 20 May 2007). The ACCA, a member of the AT network, offers a Certified Accounting Technician (CAT) designation which has both examinations and practical experience requirements. Candidates can study full or part-time at a college, or training centre and by distance learning or online, then sit the examinations and keep a training record of at least one year's practical accounting experience. Similar to its UK counterparts, AAT Australia recruits members through examinations and practical experience requirements. Candidates can also acquire the AAT Australia qualification through the skills assessment process conducted by Accounting Education Australia (AEA), a quality endorsed registered training organisation which

---

[2] It has a partner body in the Institute of Chartered Accountants in Ireland (ICAI).
[3] It is supported by CPA Australia, the Institute of Chartered Accountants in Australia (ICAA) and the National Institute of Accountants (NIA).

provides individuals with the opportunity to benchmark their current skills and competencies. All these routes do provide opportunities for the ATs to continue their study and training to become professional accountants.

THE NEW ZEALAND SITUATION

In New Zealand, an Accounting Technician (AT) College was introduced in 1995 as part of the New Zealand Institute of Chartered Accountants (NZICA)[4]. The inclusion of the AT professional qualification was a reflection of the New Zealand professional bodies' initiative to follow current education trends in the profession as recommended by Lothian and Marrian (1992), the IFAC's International Education Guideline 9, and the AT structure that existed within the profession in the United Kingdom (Maltby, 1996). Admission to the AT College is a four-year process that includes three qualifying components: (1) two years of academic study; (2) one year of general practical experience and one year of specified practical experience under the oversight of an Institute-registered member; and (3) a professional competence programme which involves passing a Professional Competence Examination (Institute of Chartered Accountants of New Zealand, 2002).

The academic requirement can be acquired by completing the New Zealand Diploma in Business (NZDipBus)[5], which is currently offered by New Zealand polytechnics, some private training organisations, and until recently, two universities. The NZDipBus is a two-year full time programme consisting of twelve papers. In order to fulfil the academic requirements of the AT College, the following papers must be included in the NZDipBus (ICANZ, 2002, p.5):

100 Accounting Principles	140 Business Communication
101 Accounting Practices	150 Computer Concepts
110 Introduction to Commercial Law	201 Financial Accounting
120 The Economic Environment	202 Management Accounting
130 Organisation & Management	

and one of: 203 Business Finance, 205 Internal Auditing, 206 Taxation

---

[4] Previously known as New Zealand Society of Accountants (NZSA) and Institute of Chartered Accountants of New Zealand (ICANZ) (since 1 October 1996). On 3 August 2005, it changed to the current title – New Zealand Institute of Chartered Accountants (NZICA).

[5] As a result of criticisms of the New Zealand Certificate in Commerce (NZCC) in the mid-1980's, a new qualification was developed - the National Certificate in Business (NCB), supported by a number of professional bodies such as the NZ Society of Accountants (NZSA) *[now the New Zealand Institute of Chartered Accountants]*, the Bankers' Institute (now the Australasian Institute of Banking and Finance) and the Institute of Chartered Secretaries and Administrators (now the Chartered Institute of Corporate Management). The first programmes were offered in 1987. In March 1995, the NCB was renamed the New Zealand Diploma in Business since the term better represents the level of the qualification (Wells, 2003, p.72).

and two optional papers, with at least one of these at 200 level

The owner of the NZDipBus, however, is the New Zealand Qualifications Authority (NZQA), a government department. It is responsible for maintaining the currency and quality of the programme. The NZQA duties range from developing course prescriptions, to managing the external moderation of the qualification to ensure a consistent quality of delivery by providers. In contrast to its accreditation review of tertiary academic programmes for the chartered accountancy qualification, NZICA neither accredits the organisations running the NZDipBus, nor produces statements of learning outcomes (SLOs) for the required AT topics in the programme. Instead, NZICA uses the broad list of outcomes for the NZDipBus as the benchmark for its AT College requirements. Nonetheless, it is noteworthy that a number of the skills and attributes of the NZDipBus graduate (such as communication skills, problem solving skills, and ethical awareness) feature in the profiling of an AT in the literature (see for example, AAT, 2002; IFAC Education Council, 1999). The NZDipBus outcomes identified by NZQA are as follows:

A graduate of the New Zealand Diploma in Business will:
1. in a range of diverse and changing organisational settings, effectively be able to:
   a. add value by applying specific business skills;
   b. apply a range of interpersonal and communication skills;
   c. apply critical problem solving skills with initiative and judgement;
   d. recognise ethical and cultural issues inherent in decision making; and
   e. work independently and within teams of diverse people.
2. have appropriate skills, research abilities and knowledge to pursue further study and professional development (NZQA, 2005).

SKILLS, ATTRIBUTES AND KNOWLEDGE REQUIREMENTS FOR ACCOUNTING TECHNICIANS

The world has been changing constantly in the last few decades. Globalisation, rapid technology development, socio-economic reforms, intense competition, proliferation of regulations, not to mention organisational restructures (Arthur Andersen et al., 1989) have huge impact on the business community. In particular, the massive expansion of the financial services sector has led to a shortage of suitably qualified finance/accounting personnel. Rapid environmental change has created new demands for a diversity of services requiring broader and more flexible skills. Concerns about accounting education have been expressed by policy makers, educators, researchers, practitioners, and the general public regarding the education

and training of such quality professionals. Calls have been made to address the decline in the quantity and quality of accounting students and the deficiencies in the curriculum and pedagogy of accounting programs. Reports into such issues have called for the introduction of competence-based accountancy programs (see AAA 1986; Arthur Andersen & Co. et al. 1989; AECC 1990; IMA 1994; and Albrecht and Sack 2000) to ensure that prospective professional accountants and their supporting personnel have the requisite skills and knowledge to meet the challenges in today's business environment.

In the skills shortage environment, accounting technicians can play an integral role in the overall business management function. However, they need to be equipped not only with core technical accountancy skills, but also vital complementary skills in areas such as IT, communication, leadership and time management" (AAT Australia, 2008), as employers tend to seek employees who are multi-skilled within their own specialist area of expertise. Possessing a variety of skills and attributes such as analytical and problem solving skills, communication (oral and written) skills, self-motivation and ethics awareness (Victoria University of Wellington, 2003) will certainly be more employable in the current environment.

 "Competence", according to the IFAC Education Committee (1998, p.1), is "the ability to perform the tasks and roles expected of a professional accountant, both newly qualified and experienced, to the standard expected by employers and the general public." Achieving this requires the cooperation of three components in three different settings: (1) educational institutions developing the necessary capabilities, (2) the workplace cultivating the practical experience, and (3) professional education programmes conducting the tests of professional competence (IFAC, 2003). As such, being "competent" is not just about being able to do a job in a given situation, but being able to transfer skills to different situations and contexts and to deal with contingencies and uncertainties (Purcell, 2001). The "competence drive" is to produce accounting graduates who are able to add value to their professional work by displaying the knowledge and ability to provide answers to the "why", "how", and "what if" questions. Implicitly and explicitly, it "encourages professional bodies and those who have a vested interest in the training of accountants to link accounting curriculums more closely with workplace requirements to help ensure that the knowledge and capabilities required of professional accountants remain relevant" (NZICA, 2003, p.53).

The IFAC guideline on the education and training of technical accounting staff (IFAC Education Committee, 1999) provides guidance on the education and training required for technical accounting staff. It highlights that:

> Technical accounting staff is the foundation of any accounting system. In many cases it is the shortage of competent staff at this level that is the main constraint in developing an effective accounting service. The design of sound education and training schemes for technical accounting staff is therefore crucial. (1999, p.9)

Since technical accounting staff work in all types of organisations in all sectors of the economy, and undertake a wide range of work from basic accounts clerk to more senior duties such as credit controller. Given the range of duties, together with the extent of change in the business environment, the Guideline states that:

> It is vital that the education and training of technical accounting staff should extend beyond developing the skills required to carry out a narrowly defined given task in a competent manner. Flexibility and the development of transferable skills are essential. Accounting tasks need to be understood in their wider business context if they are to be performed effectively… In addition to basic accounting and IT skills, competent technical accounting staff will need to be effective communicators, orally and in writing. The ability to develop effective working relationships with other members of the organisation is also important. (1999, p.5)

The competences highlighted by the Guideline closely resemble those emphasised in the major reports surrounding the calls for accounting education change at the CA level in the United States (see, for example, Arthur Anderson et.al., 1986; AECC, 1990; Albrecht & Sack, 2000). Nonetheless, accounting education, whether to produce graduates for the professional accountant career pathway or the AT route, has to maintain currency in and relevance to the nature of work demanded by the employers/workplace.

Prior Studies

Prior research conducted in New Zealand on accounting technicians has examined academic training, employer perceptions, as well as professional aspirations. Nowlan (1996) found that the educational and practical work experiences of ATs were similar internationally and the majority of ATs were satisfied that courses they had attended met their needs in the workplace and that the compulsory CPD requirement was the right move. This was supported by McIntosh (1996) in her survey of accounting technicians and employers. She found that the academic training her technician-respondents received through the New Zealand Diploma in Business (NZDipBus) was well-suited to prepare them for their workplace. She also found that small and

medium CA firms and corporate and public sector employers of accounting had expressed interest in employing ATs at their organizations. As such, she predicted that the changing nature of accounting work would affect the nature of AT's work in the future. In her survey of accounting major students from three separate NZDipBus providers, McIntosh (1997) also found that 45% of the students surveyed definitely intended joining the AT College with a further 28% considering joining. She thus concluded that many undertook NZDipBus studies to advance their career in accounting and gain membership of the AT College in particular.

Research conducted in the UK also covered similar areas but tended to focus more on the provision of the continuing professional development (CPD) component. In the late 1980s, the AAT, in conjunction with the Plymouth Business School, conducted a research surveying the views of both accounting technicians and employers on the necessity of CPD and the professional body's role in supporting this component. It was found that CPD was vital for upgrading the task role of accounting technicians and there was a very high level of consensus over priority areas for further development of technical and interpersonal skills (Chaston & Mangles, 1991). Subsequent research conducted by the AAT in 2001 showed that "96% of its full members consider continuing professional development (CPD) as very important, if not vital, to their long-term career development and employability" (AAT, 2002). The CPD programme offered to AAT members was cited as one of the main reasons people sought membership. In another AAT research study in 1998, the Association surveyed 200 UK financial directors and found that 90% commented positively on the improvement in the skills of accounting technicians over the previous five years (AAT, 1998). A 2002 AAT survey found that employers were looking for staff who not only had good technical accounting skills, but also skills in personal effectiveness, communication, time management and information technology. Furthermore, nearly 50% of the employer respondents believed CPD had improved their business, while a third claimed it had helped reduce staff turnover. CPD was also linked to lifelong learning and its associated benefits.

RESEARCH DESIGN

The aim of this research is to ascertain the extent to which the current accounting curriculum meets the needs of the accounting technician's role in the workplace. To examine whether the academic programmes the ATs complete are meeting the needs of this group of accounting para-professionals, an opinion survey of accounting technicians was conducted to determine (1) the type of duties they perform in business, (2) specific skills, attributes and areas of knowledge

important to their work, (3) the percentage of accounting technicians who have completed the NZDipBus, and (4) the papers within the Diploma that were most useful for their employment. This study also investigates the degree of importance placed on various skills, attributes, and knowledge by New Zealand employers of accounting technicians.

Sample Selection

The Institute was approached to provide the names and addresses of the last five hundred and forty members who joined the AT College. A number of members of this College who joined when it was first established in 1996, were senior employees of organisations; they had not been members of the Institute due to lack of formal qualifications (Hayes 1999). The reason for selecting the most recent members was to try to avoid including any of the members who had not gone through the normal route to membership in the sample.

Research Instrument

A mail survey was used which consisted of two different questionnaires. One questionnaire was for the accounting technician to complete, the other was for their employer. Each group was asked to complete and return their questionnaires independently. The questionnaires had two sections. The first section contained questions of a more general nature but were specific to a particular group of respondents; whereas many of the questions in the second section were common to both questionnaires. Where appropriate, a five point Likert Scale was used for scoring answers.

One hundred and seventy nine useable AT responses (response rate 33.1%) and 114 useable employer responses were received. It is not possible to measure the response rate of employers as some accounting technicians may not have given their employer the questionnaire to complete. Five surveys were returned 'no longer at this address'.

RESULTS, ANALYSIS AND DISCUSSION

Range of Duties Accounting Technicians Perform in Business

The employer responses indicate preparing financial accounts and statements, recording transactions and providing financial and management information are the tasks most commonly assigned to ATs (see Table 1). This supports Franks (1996) view of an AT's role in organisations. Approximately a third of the employer respondents involved their ATs in credit

control or auditing tasks, and only a quarter of the respondents assigned their ATs working capital management or product costing tasks.

Table 1. Duties/tasks undertaken by AT employees

Duty/task undertaken by AT employees	Percentage (%)
Preparing financial accounts and statements	92
Recording financial transactions	89
Providing financial and management information	88
Managing accounting systems	78
Payroll	63
Advising of taxation effects	62
Contributing to business planning and control	60
Implementing and supervising IT systems	50
Undertaking credit control	35
Auditing	33
Working capital management	25
Product costing	21

These results possibly reflect the respondent employer's type of organisation. Of the 114 employer responses, 62 (54.4%) were from Chartered Accounting Firms, and 52 (45.6%) from non-Chartered Accounting Firms. The industry most frequently represented within this 45.6% was "Finance, Property and Business Services" (20%).

The Chartered Accounting firms employed between two and four qualified Chartered Accountants and between two and four qualified ATs in their accounting team of between 10 to 15 people. The non-accounting firm respondents employed between five and nine accounting staff; but with no more than one qualified Chartered Accountant and/or one Accounting Technician. Further, the non-accounting employer responses indicated they assigned more varied roles, such as business planning and control and implementing and supervising IT systems, to their AT employee. Many of the AT respondents reported to a senior accountant, although the survey also revealed that some accounting technicians have sole charge over the accounting functions of the firm for which they work.

The AT respondents were asked how important certain accounting areas covered in their formal education are for their work, and how well these topics were covered in their academic study. For both questions a five point Likert Scale was used with five indicating the topic was "very important", and one "not at all important". In terms of degree of coverage, the scale varied from five "excellent coverage", to one "no coverage". The responses are summarised in Table 2.

Table 2. Topic importance and degree of coverage in formal education.

	Importance			Coverage			
	Mean	*Std Dev*	*Rank*	*Mean*	*Std Dev*	*Rank*	*% change in means*
Preparing financial stms	4.60	0.89	1	4.04	0.76	1	12%
Recording financial trans	4.46	0.95	2	3.91	0.79	2	12%
Financial analysis	4.26	0.94	3	3.77	0.91	3	12%
Internal controls	4.07	1.00	4	3.21	1.01	6	21%
Tax management	4.00	1.33	5	3.26	1.18	5	19%
Budgeting	3.93	1.15	6	3.02	0.98	7	23%
Working capital mgmt	3.42	1.28	7	2.99	1.02	8	13%
Payroll	3.36	1.23	8	2.08	1.00	11	38%
Credit control	2.98	1.24	9	2.54	1.07	10	15%
Auditing	2.84	1.34	10	2.71	1.27	9	5%
Product costing	2.77	1.25	11	3.27	0.98	4	-18%

The order of importance the AT respondents assigned to the preparation of financial statements, recording of financial transactions and financial analysis at the higher end of their ranking and auditing and product costing at the lower end, reflect the Employer respondents assignment of tasks to their AT employees (see Table 1).

However, the ATs considered working capital management more important and payroll less important than might be expected given the tasks that are typically assigned to them. In most cases the ranking of importance of an accounting area and the degree to which it was covered in formal education are similar. Product costing was the key exception, ranking eleventh in importance and fourth in coverage, suggesting an overemphasis in academic programmes relative to its importance in the work place. Notably, no topics received excellent coverage; overall the AT respondents considered the topics received fair to good coverage. Further, ten of the eleven topics scored a higher mean for importance than for coverage which is consistent with a number of accounting technicians stating that their formal academic study did not adequately prepare them for the work environment. For example, internal controls ranked fourth in importance, but only scored 'fair' in coverage.

The Skills, Attributes and Knowledge of Accounting Technicians

Both the employer and AT questionnaires listed twenty-one specific skills, attributes and areas of knowledge and the respondents were asked to indicate how important each factor was to the work of the accounting technician. The results from both the AT and employer surveys are shown in Table 3.

Table 3. The importance of specific skills, attributes and knowledge.

	ACCOUNTING TECHNICIANS			EMPLOYERS		
	Mean	*Std Dev*	*Rank*	*Mean*	*Std Dev*	*Rank*
Sense of integrity	4.80	0.47	1	4.86	0.35	1

Most of the skills, attributes and areas of knowledge were considered by both accounting technician and employer as either fairly important or very important to the AT. None of the factors were considered to be 'not important'. The average difference between the means of all the AT and employer responses is only 1%. However, the employers' ranked 'team working skills' fourth which is considerably higher than the ATs who ranked it tenth. Integrity, verbal communication and listening skills were considered the most important, by both groups of respondents, with two further aspects of communication listed as very important. This reinforces the emphasis placed on communication in the literature and the notion that these are important skills for more than just those at the Chartered Accountancy level. It is Interesting that 'technical accounting skills' were ranked fifth and sixth by the ATs and employers respectively; below 'integrity', 'verbal communication' and 'listening skills' in importance. This finding is consistent with the literature (see Arthur Andersen et al, 1989 and Rainsbury and Brown, 2001) but a little surprising given that the accounting technicians' work is of a more technical nature.

Written communication, ethical awareness, team working skills and organisational knowledge were four areas where the employers' mean ranking was two or more places different to the ranking assigned by the ATs. In particular, it appears the ATs did not see themselves as

needing team working skills to the same extent as their employers. However, there were consistently low rankings for supervisory skills, knowledge of the general economic environment and word processing skills in both survey groups' responses. If accounting technicians do not generally have line responsibility for other staff they would have less need for supervisory skills, an assumption that is also supported by the high ranking (6+) that the ATs gave to working independently. The more technical rather than decision making nature of their role would suggest knowledge of the general economic environment is not one of the more critical areas of knowledge to possess. One hundred and thirty-six (76%) of the ATs respondents report to a more senior accountant or CA.

One particular area that has been given increased emphasis recently by both professional bodies and businesses generally, did not feature as prominently as expected. In the literature (see for example Chaston and Mangles, 1991) CPD is considered very important to the career development and employability of accounting technicians. The diversity of AT roles and the various levels of responsibility they can have in the workplace makes CPD important as it ensures they keep their knowledge current in all areas and enhances their transferability. As Chaston and Mangles (1991) point out, CPD plays a vital role in upgrading the task role of ATs; an incentive for employers to encourage AT participation. Nonetheless the AT and Employer respondents to this survey ranked CPD's importance sixteenth and fourteenth equal respectively.

Ethical awareness, interpersonal skills and emotional intelligence were some of the other skills, attributes and areas of knowledge considered important in the literature but were ranked relatively low in these surveys. Although ATs appear to be largely involved in more routine tasks such as recording financial transactions and not the more judgmental areas such as auditing, these could be expected to be important features for any employee in an organisation.

The AT survey asked respondents to indicate how well each specific skill, attribute and area of knowledge listed was covered in their formal academic study. Again a five point Likert Scale was used with five indicating "excellent coverage", and one "no coverage". Table 4 shows the importance the AT respondents place on specific skills, attributes and areas of knowledge, together with the degree of coverage of these in their formal academic study. Consistent with their other responses, most of the factors that the ATs considered important to their work, did not rate high on coverage in their academic education. For example, listening skills, which were

rated third in importance, only ranked thirteenth in degree of coverage. Most factors had means suggesting fair coverage with some bordering on poor coverage; none of the factors had a mean indicating excellent coverage.   The average mean for importance was 4.38, while the degree of coverage had an average mean of 3.25; a difference of 26%. It appears that although many of the specific skills, attributes and areas of knowledge listed in the survey were considered important to the ATs work, the areas were not particularly well covered in their formal academic education. These findings were supported by some of the ATs' comments.

A substantial number of accounting technicians stated that their formal education did not prepare them for the demands and challenges of work. Specifically mentioned were some very basic skills, such as balancing a cheque book, basic grammar and spelling skills, to more advanced areas such as accounting software skills, and a working knowledge of specific taxes such as Goods and Services Tax. The majority of ATs considered most of their learning was achieved on the job and that a lot of the theory they learnt in their academic qualification was not relevant to the work they were doing.

Table 4. Importance and degree of coverage of specific skills, attributes and areas of knowledge

	Importance			Coverage			% change in means
	Mean	*Std Dev*	*Rank*	*Mean*	*Std Dev*	*Rank*	
Sense of integrity	4.80	0.47	1	3.52	0.96	6	27%

Supervisory skills	3.91	1.04	19	2.5	0.96	21	36%
Know. Gen. economic env	3.87	0.85	20	3.32	0.94	8	14%
Word-processing skills	3.43	1.01	21	2.87	1.13	19	16%

More positively, a few accounting technicians commented that their formal study gave them a grounding and understanding in what accounting and business is all about, while others acknowledged that their formal academic study gave them both research skills and exposure to a broad range of situations that they do not receive exposure to at work. Furthermore the respondents said such coverage gave them confidence to solve more complex issues, or to argue a case with conviction.   One accounting technician commented that those without academic qualifications tend to lack this confidence.

Employers were asked to indicate the importance they placed on the same list of specific skills, attributes and areas of knowledge, together with the degree of strength displayed by the AT employee(s) in these areas.   A five point Likert Scale was used, with five indicating the AT employee was "very strong" in this area, and one indicating the AT employee was "very weak" in the area. Table 5 summarises the results.

Table 5. The strength AT employees display in specific skills, attributes and areas of knowledge

	Importance			Strength of AT			
	Mean	*Std Dev*	*Rank*	*Mean*	*Std*	*Rank*	*% diff means*

Willingness to undertake prof dev	4.25	0.67	14=	4.34	0.62	5=	-2%
Working know. Comp. tech.	4.25	0.62	14=	4.23	0.66	11	0%
Organisational knowledge	4.20	0.69	16	4.24	0.65	9=	-1%
Goal setting skills	4.06	0.77	17	3.95	0.71	17	3%
Creative thinking skills	4.03	0.76	18	3.81	0.75	19	5%
Know. Gen. economic env	3.75	0.81	19	3.87	0.77	18	-3%
Supervisory skills	3.73	1.06	20	3.80	0.85	20=	-2%
Word-processing skills	3.50	0.91	21	3.80	0.84	20=	-9%

The difference in ranking between the importance of a factor to the work of the AT employee, and the degree of strength the AT employee displays in the area is notable. However the lowest mean value for degree of strength is 3.80 and as 4 represents 'fairly strong' the employers

clearly consider their ATs have strengths in many areas. For example, verbal communication is ranked second in importance, but only fifteenth in terms of the AT's strength. However, although ranked fifteenth, the mean is still 4.12, signifying the AT displays this skill 'fairly strongly' in the workplace.

Supervisory skills and word processing skills are the lowest ranked factors both in importance and AT strength. Nonetheless the means for these skills are still relatively high. These findings suggest employers consider their ATs have strengths in all the listed skills, attributes and areas of knowledge which is consistent with many of the general comments they made in their responses. In particular, they considered accounting technicians were highly regarded staff members because of the value and skills they bring to the organisation. Indeed employer respondents cited the ATs' educational qualifications; the ethical attributes associated with their membership of a College of the NZ Institute of Chartered Accountants; and the perceived knowledge they have of current accounting issues, as the most important reasons for employing an AT.

Generally the AT respondents considered the skills, attributes and areas of knowledge listed were important to their work, but they had not necessarily received adequate coverage in their formal academic study. However, the employer respondents considered their AT employees displayed a relatively high degree of strength in these same areas. One explanation for these apparent differences in response is that accounting technicians bring their life and previous work experiences to their current employment. Many accounting technicians are mature adults and their life and previous work experiences may have added considerable strength to their current performance.

NZDBus papers ATs found most useful

Accounting technicians who have either completed, or partially completed the New Zealand Diploma in Business (NZDipBus), were asked to indicate how useful their completed NZDipBus papers were to their employment. Sixteen NZDipBus papers were listed in the questionnaire. These were chosen on the basis they were the papers most likely to be chosen by an accounting student. (When collating the results, no other NZDipBus paper was listed in any significant quantity in the "other" column.) Again a five point Likert Scale was used ranging from five "very useful" to one "never useful".

Over 53% of the AT respondents had either completed, or partially completed, the NZDipBus as their tertiary qualification to satisfy the academic requirements of the AT College. Forty-five percent had either completed, or were in the process of completing, a business degree majoring in accountancy. Seven percent of the respondents did not have any academic qualification. The responses of the AT respondents who had either completed, or partially completed, the NZDipBus are summarised in Table 6.

The AT respondents were also asked to indicate the main areas in which they work. The two most frequent areas of work were Financial Accounting (80% worked in this area) and Taxation (60%). This result supports the range of duties accounting technicians typically perform in business (see Table 1). It is also not surprising that the two NZDipBus papers identified as the most useful were Financial Accounting and Accounting Practices.

Table 6. The degree of usefulness of NZDipBus papers

NZDipBus Paper *			
	Mean	*Std Dev*	*Count*
201 Financial Acccounting	4.69	0.55	102
101 Accounting Practices	4.62	0.63	106
206 Taxation	4.56	0.80	84
210 Law of Legal Enterprises	4.56	0.53	9
100 Accounting Principles	4.50	0.72	108
150 Computer Concepts	4.22	0.98	95
205 Auditing	4.07	0.83	14
203 Business Finance	4.04	0.96	51
202 Management Accounting	4.00	1.13	96
140 Business Communication	3.91	1.02	98
130 Organisation and Management	3.53	0.96	98
211 Business Law	3.52	0.83	33
110 Introduction to Commercial Law	3.45	0.96	103
160 Quantitative Business Methods	3.40	1.07	52
120 The Economic Environment	3.35	0.92	92
141 Marketing	2.79	1.04	47

 * The bolded papers are mandatory if the NZDipBus is to satisfy the AT College academic requirements. Students must also include one of 203, 205 or 206.

On-the-other-hand, the areas that the least number of AT respondents worked in were Marketing (4%) and Law (5%) and this is reflected in the papers accounting technicians found least useful in their employment. Although 210 Law of Legal Entities has a mean score of 4.56, only nine accounting technicians had taken this paper suggesting the paper is not seen as

important at the study planning stage. Both Commercial Law and Marketing papers are among the bottom four papers listed for usefulness and indeed many of the larger firms probably either employ separate legal and marketing staff, or use other specialist firms to undertake these duties for them.

It is noteworthy that only 13% of the AT respondents indicated they worked in the Auditing area, which is consistent with only 13 taking the auditing paper in the NZDipBus. At present auditing appears to be an area that ATs are either not typically assigned to or they are choosing not to be involved with.

More general information regarding ATs

The most common reasons the accounting technicians gave for joining the New Zealand Institute of Chartered Accountants were:

- o Recognition of personal experience and education – 83%
- o Signifies membership of NZ's professional accounting body – 77%
- o Improved employment prospects – 59%.

Approximately 23% of the AT respondents were planning to use the AT College as a stepping stone to joining the CA College. Whereas nearly 77% were planning to remain in the AT College, (a few were undecided). There were a number of general comments in the AT Survey from accounting technicians expressing concerns about the difficulties of going from the AT to the CA College. These accounting technicians considered the step between the two Colleges too large, with many stating that it is difficult to complete the required academic study for the CA College while working full-time. There were a number of suggestions that the New Zealand Institute of Chartered Accountants needs a qualification between AT and CA. Associate Chartered Accountant (ACA) had previously been the ultimate professional qualification of the New Zealand professional body and the ACA College was retained for a short period after the introduction of the CA College in 1994.

Interestingly in November 2006, the Institute reopened the ACA College and by June 2007 (NZICA Board Update, 25 June 2007) they had received a total of 589 applications for admission. An analysis of these applications shows 305 are from existing members (most likely all AT College members) with 263 of them seeking admission through the special entry route. Of the 284 non-member applications received, 190 are seeking admission through the special

entry route. The special entry route is open until 1 November 2008 and allows candidates to have either a degree or NZDipBus or courses/papers deemed comparable to one of those qualifications with no requirement to have specific accounting or business courses included in the academic component. Further, the special entry route does not require candidates to show specific work experience. Depending on the candidate's academic component they simply need to show evidence of a minimum of three years (degree or equivalent) or five years (NZDipBus or equivalent) recent work experience in an accounting or accounting related role/s, with competence in at least two areas.   The ACA designation is positioned between AT and CA.

CONCLUSIONS

There is mounting evidence that ATs perform a number of different roles in a variety of organisations. Franks (1996) describes accounting technicians as 'middle-level' accountants; that is, providing support services to both chartered accountants and managers. The findings of this research that 76% of the AT respondents report to a senior accountant/ chartered accountant, and that these employees undertake many duties, support Frank's observation. There are also indications that their duties are of a more technical, rather than decision-making nature. This research identified recording financial transactions; preparing financial statements; providing financial and management information; managing accounting systems; and advising on taxation effects as the duties most commonly undertaken by ATs.

It appears the 'soft skills' identified as important to Chartered Accountants (members of the CA College) are also important for accounting technicians and the roles they play in organisations. The finding that both the accounting technicians and employers consider integrity, communication skills and problem solving skills to be very important suggests that educational programmes for accounting technicians need to cover more than just the basic technical accounting skills. While employers consider their AT employees generally display strengths in the 'soft skills' area, the accounting technicians considered the coverage of these skills in their formal education was inadequate.

The qualifications of the sample population used in this study are not necessarily representative of the entire AT College, as many of the early members were admitted to the AT College on the basis of their work experience and not tertiary qualifications. Nonetheless in this study over 53% of the AT respondents indicated they had completed or partially completed the NZDipBus with 45% having completed or partially completed a business degree majoring in accountancy.

However, only 23% indicated they were intending to proceed to the CA College. This indicates that while the NZDipBus is still the preferred academic pathway for the majority, many accounting technicians are completing degree programmes without necessarily intending to proceed to the CA College. One explanation could be that the AT and/or their employer are placing importance on gaining a degree qualification in addition to acquiring the AT professional membership. It might also reflect the importance being placed on the "soft skills" which may not be covered as well in the more technical Diploma programme.

The evidence provided by this study (and others) indicates accounting technicians fill a market niche and are valued employees. Employers consider accounting technicians bring a number of different skills, attributes and areas of knowledge to organisations and accordingly assign them a range of duties. Nonetheless, the AT College does not have a high profile in New Zealand with it often seen as merely a 'stepping stone' and its members the 'poor cousins'. There is scope for the image of the AT College to be improved with membership promoted in its own right, as a brand that adds value to business. There is clear evidence Australia is going to adopt this approach, with the three professional bodies collectively supporting a $1 million development funding proposal for the restructuring and development of the AAT. New Zealand, on the other hand, appears to have moved their attention to a third tier positioned between the CA and AT Colleges; the ACA College.

Perhaps not surprisingly, the findings of this research suggest that all the NZDipBus courses are of some use to accounting technicians, but those that proved to be most useful were directly related to the accounting areas they typically work in; for example financial accounting, accounting practices and taxation. This suggests there is some alignment of the NZDipBus curriculum with the foundation technical skills and knowledge required by ATs. However, the ATs perceptions that their accounting education did not adequately cover the required skills, attributes and knowledge needed in their work environment is a concern. It is imperative that the curriculum content of programmes, particularly vocational programmes such as the NZDipBus are kept relevant to the changing business environment and workplace. Because the NZDipBus is owned and controlled by NZQA, a Government Department, the programme's curriculum will not be able to respond quickly to change and any curriculum review will require the Government, professional bodies and tertiary institutions to collaborate. There are also indications from these research findings that a number of accounting technicians undertake accounting studies at degree level, which is beyond the minimum level required for AT College

membership, and yet they do not intend proceeding to the CA College. This suggests some students are not only seeking AT membership but also a University education and qualification. The sub-degree Diploma may be losing currency in the accounting qualification market.   It may also follow that the ACA College, which under its standard entry requirements requires the completion of a degree, will gain favour over the AT College. However the market reaction, both nationally and internationally, to New Zealand's three tier professional body structure is still uncertain.

BACK TO THE BASIC: ACCOUNTING AS A NUMBER-CRUNCHING COURSE

Sony Warsono
Arief Surya Irawan (Corresponding author)
Arif Darmawan
Muhammad Arsyadi Ridha

Abstract

Accounting has long been known as a number-crunching course however its existing teaching model considers it as a language of business focusing on rules. This paper uses mathematical perspectives in the teaching of the financial accounting course. Mathematics-based accounting learning enables students to understand accounting easier because it is rational and makes sense. This paper discusses the rules of debit and credit based on mathematic theorem, namely the ordered pairs of the group of differences construction. It uses the accounting equation as a means of identifying various possible business transactions. The mathematics-based accounting learning is in accordance with the firstly published Mathematics book written by Luca Pacioli. This paper also suggests that at least accounting textbooks dedicate a specific chapter to discuss measurement issues in accounting principles courses.

Keywords: A number-crunching course, expanded accounting equation, transactions, measurement in accounting

A. Introduction.

The accounting education has been internationally a subject of criticisms (Duff and McKinstry 2007) as it is considered passive (Bonner 1999) and unable to catch up with current development in business to the extent that students can hardly receive any perfect picture of the real business world (Adler 1999). It is also criticized because it depends too much on memorizing and focusing too much on rules (Demski 2007; Fellingham 2007). As a result, most accounting books are similar to one another (Sullivan and Benke 1997) which in turn make accounting less than appealing to the student. Furthermore, researchers and accounting

educators pay more attention to their careers but neglect the contributions of accounting to academic field (Fellingham 2007).

Three studies published by AAA, namely Bedford Report (1986), Big Eight White Paper (1989), and Albrecht and Sack Study (2000) discussed the importance of developing new models in accounting education (see Clevenger et al. 2006). Some researchers also pay attention to the development of accounting education models. Duff and McKinstry (2007, p.205) offer the use of SAL (Student Approaches to Learning) because it "provides accounting educators with a range of models, instruments, and perspectives to evaluate and integrate their teaching interventions so they may achieve intended outcomes". Other researchers suggested the use of information technology to improve the effectiveness of accounting study (Elliot 1992; Mohamed and Lashine 2003; David et al 2003; Goldwater and Fogarty 2007). Recently, Fordham and Hayes (2009, p.187) found that "paper color did have a significant effect on student performances". It shows that the topic of accounting education is still and will always be an interesting topic to be discussed. Accounting was documented for the first time in Luca Pacioli's mathematic book (Weis and Tinius 1991).

The use of double entry system reflects the application of mathematics in accounting. However, mathematics-based accounting learning is hardly found in modern textbooks. This paper discusses the use of mathematics-based learning in the financial accounting courses, especially an accounting principles course. The mathematical perspective in accounting education is interesting for several reasons. Firstly, mathematics is elegant (Hatfield 1924). Secondly, double entry system that has been tested for 5 centuries is based on mathematics (Fellingham 2007). Thirdly, most students have been familiar with mathematics for a long time. Fourthly, "humans are born with the capacity to do simple math." (Hauser 1999, 1483). This paper discusses the accounting principles course because the course is studied by accounting students as well as non-accounting students.

The remainder of this paper is presented in five sections. The first section discusses the mathematical rationality of the accounting equation in which the double entry system is based on. The second section discusses the recording of transactions as an input in accounting. The third section, based on the ordered pairs of the group of differences construction, describes the rationality of the rules of debit and credit. Using the accounting equation, the fourth section identifies types of business transactions. The final section discusses the importance of specific discussion about measurement in one of chapters in the accounting principles course.

B. Rationalizing Accounting Equation

The Accounting equation is one of the important topics in accounting. The elements of the equation are "the building block with which financial statements are constructed – the classes of items that financial statements comprise" (FASB 1985, par.5). Normally the accounting equation consists of five elements namely assets, liabilities, equity, revenues, and expenses. Some accounting books express accounting equation as: Assets = Liabilities + Equity (Williams et al. 2005; Anthony et al. 2007), and some other books express it as: Assets = Liabilities + Equity + (Revenues – Expenses) (Horngren et al. 2002; Weygandt et al. 2008). These elements are measured in terms of a monetary unit. The rationality of this conventional equation is that assets derive from liabilities and equity. Revenues and expenses are part of equity; revenues increase equity while expenses decrease equity.

"Pacioli, like other mathematicians of his time, did his utmost to avoid even the use a symbol for minus, let alone a negative number" (Peters and Emery 1978, p.426). Thus, the accounting equation can be written as Assets + Expenses = Liabilities + Equity + Revenues. The left side of the equation reflects the uses of funds, that is to get assets and pay expenses, while the right side reflects the sources of funds, namely from third parties, equity, and revenues. When the amount total of the uses of the funds is higher than the amount total of the sources of funds, it can be concluded that something goes wrong because there is no explanation on how

the funds is acquired. The authors argue that the rationality is more consistent and easier to understand than the conventional one.

The conceptual framework of the IASB states 5 elements of financial statements namely assets, liabilities, equity, income and expenses (Alfredson et al. 2007), while the FASB states 10 interrelated elements of financial statements namely assets, liabilities, equity, investments by owners, distribution to owners, comprehensive income, revenues, gains, and losses (FASB, 1985).

Despite the facts that the boards have different elements, the balance between the left side and the right side of the accounting equations which is required by mathematics will remain the same. In the accounting learning, instructors are allowed to develop new elements which have not been determined by the standards. The FASB (1985, par.3) states that "Although the elements defined in this Statement include basic elements and are probably those most commonly identified as elements of financial statements, they are not the only elements of financial statements". Therefore, mathematics-based accounting learning invites students to understand and develop concepts rather than just recognizing rules.

C. Recording transactions

A transaction is the input of accounting. Weygandt et al. (2008, p.14) defined a transaction as: "a business' economic events recorded by accountants". Anthony et al (2007, p.31) defined transactions as "events that affect the numbers in an entity's accounting record…" Horngren et al. (2001, p.10) defined a transaction as "any event that both affects the financial position of an entity and can be reliably recorded in money term". The three definitions above need further explanation in order to facilitate students' understanding.

Based on the accounting equation, a transaction can be defined as any business event that leads to changes in the elements of the accounting equation by maintaining the balance of it. The changes of elements can be either positive or negative. Consequently, if a transaction

changes assets then other assets, liabilities, equity, expenses, revenues (or combinations of those elements) change. Thus, a transaction at least will cause 2 changes.

Presenting accounting information based on the elements of accounting equation is considered uninformative because one element can consist of various objects. For example, 2 firms A and B have equal total assets. Most of firm A's assets are account receivables, while most firm B's assets is buildings and machinery. Despite the fact that both have equal total assets, creditors assume that firm A is better than firm B in their ability to pay short-term liabilities. In order to present informative accounting information, the elements of accounting equations must be elaborated in detail in the forms of accounts. Each account should reflect a homogenous object.

As mentioned above, a transaction at least will cause 2 changes. Therefore, recording a transaction at least will involve two accounts. In accordance with the rationality of the accounting equation, there are two types of accounts namely accounts reflecting the use of funds (on the left side of the equation) and accounts reflecting the sources of funds (on the right side of the equation). Mathematically, it can be explained as follows: a transaction that involves 2 accounts of the same type will have reversed relationships. For example, the payment of salary increases salary expenses (an element of expenses) and decreases cash (an element of assets). On the other hand, the purchase of supplies on account increases supplies (an element of assets) and account payable.

D. Understanding the Rules of Debit and Credit

Modern accounting explicitly or implicitly puts the emphasis on the need of double entry accounting system in every transaction recording. It requires a balance system between debit and credit. Although double entry system has been used widely, the literatures on mathematical formulation of the double entry and its connection to the accounting are still limited. Ellerman (1985, p.226) mentioned that only few mathematic literatures connected to the mathematics-

accounting double entry, and the connection "is totally absent in the accounting literature....". Furthermore, Ellerman (1985) mathematically explained the rules of the debit and credit.

The explanation of the rules of debit and credit is as follows. Supposed, Assets = 10, Expenses = 5, Liabilities = 2, Equity = 6, and Revenues = 7. The accounting equation is 10 + 5 = 2 + 6 + 7. Based on the ordered pairs of the group of differences construction (see Ellerman 1985), the assets with the value of 10 can be recorded either at one side, i.e 14 is recorded to the debit and 4 to the credit, or 4 to debit and 14 to the credit. According to the mathematics formulation, however, the first alternative should be applied because the assets have positive value and it is located at the left side of the accounting equation. The interpretation is that 4 on the credit deduct 14 on the debit. As a result, the additional of assets is recorded on the debit while the deduction of assets is recorded on the credit. Such rules are also applicable to the liabilities for creating a balance condition. Let us consider the liability is 2 and it can be recorded either 20 on the debit and 18 on the credit or 18 on the debit and 20 on the credit. When the mathematics formulation is implemented into the double entry, the second alternative should be applied because the liability has positive value and it is located on the right side of the accounting equation. The number of 18 on the debit deducts the number 20 which on the credit. Therefore, the increase of liabilities is recorded on the credit while its decrease is recorded on the debit.

E. Understanding types of business transactions

Accounting equation can be implemented in identifying various real business transactions. If there are five elements of basic accounting equation, there will be 15 types of transactions as follows.

1. Transaction that changes assets (types A); firm A purchases supplies in cash.

2. Transaction that changes assets and expenses (type B); firm A pays employee salaries in cash

3. Transaction that changes the asset and liabilities (type C); firm A purchases supplies on credit

4. Transaction that changes assets and equity (type D); firm A issues common stocks by cash

5. Transaction that changes the asset and revenues (type E); firm A earns revenue by cash

6. Transaction that changes expenses (type F); firm A makes correcting entries for salary expenses that have been recorded as advertising expenses.

7. Transaction that changes expenses and liabilities (type G); firm A receives electricity and phone bills

8. Transaction that changes expenses and equity (type H); firm A issues common stocks in which the payment is in the form of services given by the buyer.

9. Transaction that changes the expenses and revenues (type I); firm A and firm B do service barter.

10. Transaction that changes liabilities (type J); firm A converts its short-term debt into bonds.

11. Transaction that changes liabilities and equity (type K); firm A converts its bonds into common stocks

12. Transaction that changes liabilities and revenues (type L); firm A recognizes its unearned revenues into revenues.

13. Transaction that changes equity (type M); firm A converts its preference stocks into common stocks.

14. Transaction that changes equity and revenues (type N); firm A, in the business on advertisement, distributes revenue dividends, and the stockholders directly utilize the dividends.

15. Transaction that changes revenues (O); firm A makes correcting entries for consulting revenues that have been recorded as other revenues.

By making simulation based on the accounting equation, the authors reveal the limitation of the current financial accounting standards. Several transactions given above – namely types F, H, I, N, and O are rarely found in the accounting literatures. For an education purpose, the most important thing is that the equation simulation will help students understanding the accounting concepts rather than memorizing the rules.

F. INCLUDING MEASUREMENT ISSUES IN ACCOUNTING COURSES

Accounting information should be presented in the monetary units. FASB (1984) has been implemented several different measurements and predicted to be in use for the future. Some accounting measurements used nowadays are; historical cost, current cost, current market value, net realizable value, and present-value of future cash flows. Most accounting text books, unfortunately, hardly ever discuss specifically the measurement topic. The authors so far have not found any literature discussing the accounting measurements in a particular chapter .It was dominantly discussed under other topics, so underestimate behavior among students will occur.

Nowadays, the accounting experts have been discussing the impact of the IFRS implementation in the accounting curriculum (see Nilsen, 2008). The IFRS uses accounting fair value which demands the students to understand various measurements that have been incorporated into the curriculum or that will be developed in the future. To anticipate the implementation of IFRS in America, Stone (in Nilsen 2008) recommends accounting students have strong foundation in finance and economics. Nikolai (in Nilsen 2008) mentioned that the University of Missouri is considering combining fair value accounting with IFRS into conceptual-based course because the students needs to develop more expertise. Needles (in Nilsen , 2008) said " I suspects that we will have a course in valuation related to fair value accounting….". Referring to such argumentations, it is essential to discuss about minimal fair value in a separate chapter.

It is concluded that the accounting is numeric crunching course. The application of double-entry system which based on mathematics has been proven for almost more than five centuries. When the accounting curriculum development incorporates into the international standard and future purpose, new course "Accounting Mathematics", should be given.

BENCHMARKING THE FIRST YEAR ACCOUNTING UNIT: SOME EVIDENCE FROM AUSTRALIA

Malcolm Smith, *Curtin University, Perth , Australia*
Nick Sciulli, *Victoria University, Melbourne, Australia*
Phil Ross, *University of Western Sydney, Sydney, Australia*

Abstract

Purpose – The purpose of this paper is to compare some key organisational attributes of three accounting schools located at Australian universities. In addition, the content, structure and presentation of the first-year accounting unit is examined with a view for identifying best practices.

Design/methodology/approach

Three Australian universities – one each from Sydney, Melbourne and Perth agreed to collaborate in this project. The heads of the respective schools extracted relevant data for the school comparison whilst a workshop meeting between the first year accounting unit co-ordinators undertook a content analysis from their subject guides.

Findings

The three schools had similar issues to manage including an aging staff profile, high use of casual academic staff and large student numbers across different campuses. Unsurprisingly, given the need for professional accounting body accreditation, the content of the courses was very similar. However, there were significant differences in both delivery and assessment, with potential implications for both quality and resource use.

Research limitations/implications

The size and characteristics of the three universities investigated for this project may be quite different to the wider population of accounting schools.

Practical implications

The results of this benchmarking comparison has prompted managers to be aware of the critical issues identified and take appropriate action to remedy them, For example, incentive schemes for staff to increase research outputs have been improved.

Originality/value

The authors are unaware of any previous benchmarking study comparing accounting schools at Australian universities. The findings of this project can lead to better teaching and learning outcomes for first year accounting students.

Keywords Benchmarking, Universities, Accounting courses

1. Introduction

The benchmarking project which forms the basis of this paper was initiated by discussions between the Business Deans from the three participating universities – one each from Western Australia, Victoria and New South Wales (NSW). The driving force for the initiative was a response to recommendations from the Australian Universities Quality Agency (AUQA) that universities undertake benchmarking processes as part of the quality assurance processes in the organisations. The objective of this project was to make comparisons of the content,

structure and operations of a large first year unit common to each institution. The analysis was specifically directed towards two outcomes:

(a) an indication of current best practice, which might provide the basis for improvement opportunities at each university, and
(b) confirmation that appropriate standards were being applied by each university.

The unit chosen for detailed analysis at each institution was the first year introductory accounting unit, then perceived as compulsory for all students undertaking an undergraduate business major. The Heads of School of Accounting of the three participating universities met in July 2008 and established broad areas for detailed analysis and comparison for the accounting units.

The major inputs into the comparative process were conducted via email, with source documents circulated among the interested parties; the detailed analysis of the data was undertaken in face to face meetings in September and October 2008, attended by both the Heads of School and the coordinators of the first year accounting units.

Detailed findings, and recommendations for future action, were reported to the respective Business Deans in November 2008.

The paper details differences across the three universities – designated as Case 1 (Western Australia); Case 2 (Victoria) and Case 3 (NSW)– across the areas of staff and student demographics, course content, course delivery and course assessment. The paper concludes with a summary and recommendations.

2.   Literature review.

Benchmarking is a process for identifying and implementing best practice at a particular point in time. It is equally applicable to the private sector (see Kouzmin *et al* (1999)) as to the public sector (see for example Vagnoni and Maran (2008). It is a tool that is used to not only identify best-practice but also more importantly to gain an understanding on what processes are being utilised to achieve best practice. It has been used (most likely, incorrectly), interchangeably with terms such as business process engineering , total quality management and key performance indicators (KPIs) (Alstete 2008). Benchmarking is not a new technique used in the university sector. In factor comparisons of university performance based on teaching, research student satisfaction etc is well documented and marketed as a tool for ensuring prospective students have access to some performance indicators.

Pursglove and Simpson (2007) benchmarked the performance of English universities dividing the universities into the Russell Group (research oriented universities) and the post-1992 universities. Their findings included that the post-1992 universities were more effective and efficient than the Russell group members which was at odds with the position of these universities published in league tables.

Understanding clearly what the issues are regarding the teaching of a first year accounting unit is an important topic for academics, students and prospective employers. A study by Jones and Sin (2005) found that almost a third of accounting students rated communication skills highly but that more of the non-accounting students placed communication skills first. These authors argue that unit course outlines need to incorporate generic/communication skills into ongoing student assessment. Similiarly, Morgan (1997) found that practioners assigned a high

importance to oral communication skills of active listening, constructive participation in meetings and one-to-one communication. One of the project aims for this investigation is to identify what and how students are assesses in their first year accounting unit.

Lucas (2003) found that the results of a survey of 250 000 accounting students that the variety of accounting students studying introductory accounting caused problems, because academic staff found it problematic to change their teaching styles to teach masses of students with different entry levels, where English was not their first language, age, ethnic group, gender, socio-economic status and students from non-traditional backgrounds. Given this diverse student population, Malgwi (2006) undertook a survey of 796 students at one university to ascertain whether there was merit in providing separate courses to students on the basis of whether they were intending to undertake an accounting major. The findings revealed that that there was a significant difference in the interest levels prior to and after undertaking the course. That is, the students undertaking a major in accounting had shown more interest and confidence in taking their exams than non-accounting major students, suggesting that a separate stream should be considered.

3.   Method

As a consequence of the recommendations of AUQA, the Business Deans of three Universities decided to benchmark a large undergraduate unit and this project would form the basis of future benchmarking exercises across different schools within the business faculty. To allow for reasonable comparisons, the three universities chosen were Post-Dawkins universities in that they were not established research oriented universities but rather each had a history as a teaching university.

The first year accounting unit was chosen for the first benchmarking exercise because:
* It was the largest subject offered at each location
* The unit involved the use of large number of full-time and casual staff compared with other disciplines.
* The students enrolled in the subject comprised a diverse group which included full-time and part-time students, school leavers and mature-age students, local and international students and, students enrolled to gain a major in accounting whilst other students were intending to specialise in other disciplines.

The three heads of schools were provided with some freedom in choosing what areas would be benchmarked and after numerous e-mail contact and telephone conversations it was decided to benchmark the following areas:

1. Accounting staff demographics
2. First year student accounting demographics and,
3. First year accounting unit.

Data for the accounting staff demographics was more difficult to obtain partly, because the source data was scattered across various sections of the school, faculty and centrally by the university and partly because the data was not presented in a form that was tailored for easy comparisons with other accounting schools at other universities. For the staff demographics source data was obtained from information held within the office of the head of school as well as information collected from the human resources department. Direct contact was made with other academic school staff where clarifications were required and where recently employed

staff did not have all of their previous academic history recorded electronically by the respective school.

The first year accounting student demographics data was collected from the faculty and cross-referenced with school data for accuracy. The first year accounting unit subject guide was used as the basis for a comparison of of this subject across the three universities. Moreover, a workshop was scheduled at one of the universities where the first-year accounting unit co-ordinators identified challenges in administering the unit, any major differences in unit content and how the assessment tasks differed.
The data was then tabulated in a spreadsheet format to allow for easy comparison between the three universities

4.   Findings and discussion

4.1   Accounting Staff Demographics

In terms of staff numbers, CASE   1's accounting discipline is approximately one third the size of Case   3 and CASE 2 – numbers consistent with the size of their respective student enrolments. Both CASE 1 and CASE 2 had relatively high numbers of male staff (64% and 76% respectively), whereas CASE 3 had 53% of its staff as female. The majority of staff are employed at Lecturer or Associate Lecture levels (CASE 1 55%; CASE 3 83%; CASE 2 76%) with all three universities having very low numbers of staff at the Associate Professor and Professor level; notably CASE   3 did not have any staff at these senior levels.
The age profile of accounting academic staff showed only CASE 3 to be the only employer of staff in the 20-29 age group, though this only accounted for 8% of its total staffing. All universities in the study had difficulty in recruiting and retaining younger people for a career in academia, which may reflect the requirement that prospective employees should have a higher degree qualifications (ideally a PhD) before being considered appointable. It is interesting to note that 46% of staff at CASE 1 are in the 60+ age bracket and 56% of staff at CASE 3 are in the 50-59 age bracket. These profiles will need to be monitored carefully across the sector as more staff move into retirement or elect to take an early voluntary retirement package.

Staff demographics have significant implication for the research performance of the three participating universities. Each has a high proportion of non-researchers in their accounting school, 86% for CASE 3, and 35% for CASE 1 and CASE 2. Recent literature (e.g., Smith, Whale & Noronha, 2008, for refereed publications) places all three universities in the bottom half of the rankings for Australian schools of accounting. The benchmark data provide evidence to explain such a situation:

- a paucity of senior staff across all three institutions, with CASE 3 notable in having no appointments at professorial levels;

- the absence of experienced researchers in senior positions to lead by example, and to mentor colleagues, is clearly apparent. While CASE 1 and CASE 2 both benefit from the publication activities of a small number of prolific individuals at a senior level, in their absence CASE 3 performs relatively poorly.

- since the supervision of higher degree by research candidates, particularly at doctoral level, is normally predominantly undertaken by those at professorial levels, then this impacts on HDR completions across the three universities, with again a relatively small number of individuals carrying this activity.

Thus senior positions appear to drive research performance and set the appropriate tone for the development of a research culture which attracts new research appointments. All three universities need to make senior appointments of research-active individuals if their research performance is to improve. The precarious age profile of CASE 1 also suggests that they need to appoint a number of younger research-active staff. In this regard CASE 2 is currently the stand-out performer, with a healthy cluster of young academics pursuing doctoral qualifications. However, if CASE 2, and to a lesser extent CASE 1 and CASE 3, are to hold on to their active, qualified researchers then current perceptions of their being 'feeders' for more established institutions in their States, must change.

None of the three universities made significant use of contract staff, though between 22% and 31% of staff were employed on a sessional (casual) basis. Although this percentage of sessional staff does not appear remarkably high, it may convert to a high number of sessional staff concentrated in one place. This proved to be the Case for both CASE 3 and CASE 2, with respectively 30 and 40 sessional staff commonly involved each semester in the teaching of their first-year accounting unit. These numbers have serious implications for students who require access to staff members for consultation, as well as for the timeliness of reporting between sessional and permanent staff, and ensuring consistency of presentation to students across the various sessional staff teaching across different campuses. In such situations the management of the unit becomes problematic: there was evidence from CASE 3 of the unit co-ordinator being forced to prepare and distribute detailed lesson plans to tutorial staff to maintain a semblance of consistency of delivery. Worse, some accounting subjects (though not Accounting 1) were co-ordinated entirely by sessional staff, with implications for the management approaches necessary to ensure appropriate levels of teaching and learning outcomes.

A significant difference existed in the proportions of mature age students, relative to school leavers, in the student cohort of accounting students, with 80% of CASE 1's students of mature-age compared with 48% for CASE 3 and 42% for CASE 2. Given the national trend of a declining percentage of school leavers undertaking a higher education qualification, these statistics indicate that more resources may need to be directed towards this mature-age group to meet these challenges.

4.2   First Year Accounting Demographics

In terms of local and international students CASE 2 and CASE 3 have similar cohorts (with 22% international) while CASE 1 has 11% of international students. External students are very small in number throughout, but all universities had a significant proportion of mature-age students (relative to school leavers). These demographics in the first year unit indicate the complexity of teaching a first year unit since a significant number of students will not have English as their first language and an even larger proportion may be returning to study after a significant time lag.
When combined with the problems referred to above with sessional staffing, notably lack of student access and absence of consistency, then language and confidence problems will likely pose additional pressures on the student cohort, with an impact on survival and retention.

4.3 Course Content: First Year Accounting Unit

The objectives and desired outcomes from each of the three courses are similar, with the major focus of each unit being in the areas of preparation and interpretation of basic financial information. All three units have a mix of financial accounting and management accounting with

CASE 2 and CASE 3 spending three weeks on management accounting topics whilst CASE 1 spend only two weeks on this area. The remainder of the course focuses on topics related to financial accounting with some minor variations but significantly none of the three courses focus on the concept of debits and credits. This reflects the fact that all three courses have been developed to cater to the need of students who can be either accounting or non-accounting majors.

All three universities had recognised the importance of inter-personal skills for business, and were addressing observed deficiencies in written and oral communications among the accounting student cohort. All had either begun, or were contemplating the introduction of 'skills based' units into the accounting curriculum. At CASE 3 this was limited to a single unit, teaching students practical skills for library database searches, written communication, literature evaluation, and an appreciation of cultural and ethical issues.
CASE 2's corresponding program provided three successive units which developed students' business knowledge, personal attributes and professional skills.
CASE 1's program comprised consecutive units in each year of the degree which introduced students to the concept of business, and assisted students in the acquisition of interpersonal and teamwork skills.
Thus while CASE 3's skills course primarily focused on improving students' practical skills, those at CASE 1 and CASE 2 aimed to assist the student to improve their leadership, assessment, decision-making and problem solving skills in addition to practical business skills. While the course at CASE 1 was the most wide-ranging, it also had the most serious consequences for the structure of the business degree. Because of the limited scope for elective units within the bachelor degree course, there was no longer a common core of introductory-level business subjects applicable to all business students. Thus while both CASE 2 and CASE 3 maintained a common-core, it was possible for a non-accounting major to graduate in business without ever having completed an accounting unit. (The same would be true, for example, of a non-marketing major –they need never have completed a marketing unit.)

4.4   Delivery

All three universities adopted a traditional 'lecture + tutorial 'format, with the lecture used to impart knowledge, and the tutorial having a workshop/seminar structure to follow up, clarify and provide practice exercises.
All three universities had three hours of class contact per week over a 13-week semester to complete their introductory accounting unit. However, while both CASE 1 and CASE 2 had a two-hour lecture, with a one-hour tutorial, for CASE 3 it was the opposite: a one-hour lecture and two hours of tutorial. The latter might be regarded as superior for learning purposes, especially given trends in student attendance (currently around 60% for lectures and 95% for tutorials). However, this structure is much more resource intensive, especially given the large number of tutorials necessary to conduct the CASE 3 course. A cost-benefit evaluation of this alternative structure might be beneficial.

4.5   Assessment

The assessment structure for each unit is also similar, with CASE 1 and CASE 2 having four assessment items while CASE 3 has five assessment items. The weightings assigned to the assessment items are also similar with the main exception being that CASE 3 has a final exam weighted at 45%, both CASE 1 and CASE 2 have a final exam weighted at 60%. This difference is partly attributable to the fact that the final exam at CASE 3 covers only the second

half of the course (i.e., after the mid-semester test) while for CASE 1 and CASE 2 all topics covered are examinable in the final exam.

While for all three universities assessment comprised a summation of coursework and examinations, there were differences in how this structure was implemented. For CASE 2 there was no exam threshold at all; marks across different components were totalled without weighting for whether they were individual time-constrained assessments or team-based assignments. Both CASE 3 and CASE 1, on the other hand, implemented examination thresholds – students had to achieve a certain grade on the final examination to pass the unit (45% for CASE 3 and 50% for CASE 1) as well as achieving a 50% overall mark.

The use of supplementary examinations provided a further point of difference in the area of assessment. Neither CASE 1 nor CASE 3 had any form of additional assessment for marginal failures, but CASE 2 had a non-discretionary supplementary examination for all failing candidates scoring more than 40% overall. The combination of these last two factors undoubtedly contributed to low overall fail grades in the unit at CASE 2- 21% compared to those at CASE 3 (26%) and CASE 1(32%). There was also some evidence that the assessment (assignments and examination) in CASE 1's first accounting unit were of a more difficult standard than the equivalents at CASE 3 and CASE 2; this may contribute to the higher unit failure rates experienced at CASE 1.

5.   Concluding Remarks

The benchmarking exercise has provided the opportunity to observe and analyse both the consistency and diversity of accounting offerings at three universities. The three participating universities are far from ideal for a benchmarking analysis due to differences in size, of staffing and student enrolments, and departmental discipline focus. The findings are thus difficult to generalise, but do provide interesting observations which allow the specification of recommendations consistent with the objectives of the exercise.
There are a number of issues where the problems faced by the three universities are common or similar:

- The age profile is either already precarious, or trending in that direction. Urgent attention to succession planning is required;
- The proportion of senior staff (particularly at professorial level) is consistently small, with significant implications for leadership, mentoring and research performance. Additional senior appointments, ideally of research-active staff, were required;
- The mix of students (i.e., mature-age/school leaver; local/international; major/non-accounting major) in core courses poses particular difficulties, which will impact on student satisfaction;
- The size of the first-year accounting unit required the use of sessional, rather than permanent, staff occasionally to potentially dangerous levels. The implications for both the staff co-ordination burden and the student experience should not be underestimated. For such large courses administrative assistance must be made available to avoid staff stress and burn-out.

On the other hand there were significant differences in the way the first-year accounting unit was delivered. On the face of it, the content of the units looked remarkably similar, but deeper analysis revealed differences in both the depth and mode of delivery, most notably:

- Of the three universities only CASE 1 did not have a common-core of business units. Non-accounting majors did not compulsorily complete the first accounting unit, and correspondingly accounting majors did not necessarily complete first management or marketing units;
- There were significant differences in the delivery of the first Accounting unit. Most notably, CASE 3 operated on a (1 + 2) lecture/tutorial hours split, while both CASE 1 and CASE 2 operated on a (2 + 1) split. While the former is more resource intensive, it does provide increased student contact;
- There were significant differences in the assessment of the first accounting unit. Both CASE 1 and CASE 3 instituted an exam-performance threshold, so that students with 50% overall only passed the unit if they achieved a specified mark in the exam. No such threshold existed at CASE 2; if the student accumulated 50% overall they passed the unit, irrespective of how poor their performance in the final examination;

Comparisons based on the numbers reported for student satisfaction with unit/teacher should be treated with caution, and are not detailed here, since they are based on different survey instruments. A future project might examine the development of a new instrument with common questions, in order to improve comparability.

The impact of the introduction of business skills units was already having a big impact on both course content and resource use at CASE 2 and CASE 1, though less-so at CASE 3 where student numbers had caused particular delivery problems. The scope of these skills units suggests that they provide a benchmarking exercise of their own.

On an administrative note, given that *ranking* systems for universities are in place worldwide for various purposes, then, the question of whether some universal ranking system for schools within a faculty would be a worthwhile debate. If this system were implemented then, database and reporting mechanisms across universities would need to be homogenised to allow for accurate and relevant comparisons.

1.2 Behavioral Issues in Accounting

DO ANALYSTS' RECOMMENDATIONS CONTRIBUTE TO THE IPO UNDERPERFORMANCE PUZZLE?

Yew-Kee Ho, Department of Finance, School of Business, National University of Singapore
Chee-Meng Yap, Department of Industrial and Systems Engineering, National University of Singapore

Abstract

This study examines the returns of 3,596 firms that had initial public offerings ("IPO") in the U.S. market from 1994 to 2006. At the end of the first trading day, their shares jumped an average of 18.84% above their offering price. Yet, these firms underperform the market and non-IPO firms in similar industries with similar market capitalization and book-to-market value over the next three years.

We study how analyst recommendations contribute to the IPO long-run underperformance anomaly by examining the relationship between the buy recommendations and IPO firm abnormal returns. We find that firms with high proportion of 'buy' recommendations achieve abnormal contemporaneous returns while those with a low proportion of 'buy' in the contemporaneous period underperform. The simple 'buy' recommendations appear to be reliable sources of information on contemporaneous performance of IPO firms.

We further observe evidence that analysts may be overly-optimistic in their recommendations of IPO firms' first year of going public. IPO firms receiving high proportion of 'buy' recommendations in their first year significantly underperform the market and similar non-IPO firms over the next two years. Thus, while analysts appear to be accurate about the IPO firms' prospects initially, they may have been over-optimistic causing poor future performance. This study also finds evidence of the neglect-firm effect of IPO firms that receive little or no analyst coverage. These firms exhibit a significant contemporaneous returns premium but again underperform over the long term.

1   Introduction

Stocks of Initial Public Offer (IPO) firms should perform better than the market to compensate for the risks involved. Yet, Stern and Bornstein (2005) observe that the average new issue to return 22% less compared to the broad S&P 500 Index. Loughran and Ritter (1995) also note that an investor must invest 44 percent more money in IPOs than in non-IPOs of the same size to have the same wealth five years after the offering date. These documented "IPO underperformance puzzle" thus calls for an explanation.

In this study, we investigate whether the number of positive analyst recommendations contains information about the short term and long term prospects of IPO. Also, the limited capacity of analysts results in some IPO firms receiving little or no coverage. Firms lacking coverage may be lemons that analysts selectively avoid; or they may be neglected firms that exhibit a positive returns premium. Nevertheless, the lack of coverage can contain information to investors about the IPO. In both cases, we attempt to determine if the information conveyed by analyst coverage can explain the IPO underperformance?

Our results show us that analyst over-optimism may cause IPO underperformance. Contemporaneous abnormal returns of IPO firms compared to matched firms and the market are positively correlated with the proportion of positive recommendations. However, the long term returns of these same IPO firms lag their matched counterparts and the market over a two-year return period. We also observe that IPO firms that receive little or no analyst recommendation in their post-IPO period are neglected firms that exhibit contemporaneous positive abnormal returns. They, however, underperform over a longer two-year period.

The rest of the paper is structured as follows. The next section provides a review of the extant study on the effect of analysts' coverage on IPO firms. Section 3 discusses the hypotheses development, followed by a section detailing the methodology. Section 5 provides the analysis and discussion of the results of this study. Finally, Section 6 concludes the study, together with the limitations and possible area of future research.

2 Review of the Literature

Research on the impact that analyst has on IPO returns focuses on the timing of the analyst report, attributes of the analysts reporting and the rating given to the IPO. Green (2006) finds that early access, some as soon as 2 hours following pre-market release, to changes in recommendation yields an average 2-day abnormal returns of 1.02% for upgrades and -1.50% for downgrades. Adams (2003) reports that 'buy' recommendations released within two months of IPO result in negative one year returns but the returns will be positive if the same recommendations are made more than two months after IPO. He deduces that investors view analyst coverage in the IPO aftermarket as more valuable if released later.

The attributes of analysts examined by researchers include the number of analysts covering the stock, the affiliation of the analysts and the reputation of the analyst. McNichols and O'Brien (1997), and Das et al. (2006) find that the number of analysts covering firms with positive outlook is greater as analysts avoid firms with bleak outlook and pay attention to favorable firms. Their results are consistent with the idea that analysts shy away from issuing any public opinions when their true expectations are unfavorable and choose to provide coverage for firms for which their true expectations are favorable. These firms, thus, end up with more information and better received by investors. Bradley, Jordan and Ritter (2003) introduce the "confirmation hypothesis" that market participants will find recommendations more informative when there are multiple initiations. They find a significant positive relationship between the number of recommendations and the cumulative market-adjusted returns (CMARs) during a five-day event window centered on quiet period expiration. Das et al. (2006) hypothesize that the presence of a high unexpected analyst following should correspond to a better aggregate true expectation of the analyst community about the firm's future performance. The results of the 3-year buy and hold abnormal return from their sample of 4,082 IPOs from 1986-2000 significantly affirmed their hypothesis. In contrast, Bradley, Chan, Kim and Singh (2008) find from a sample of 2,573 IPOs issued from 1993-2003 that IPOs with high unexpected

analyst coverage underperform. Their results differ mainly because Das et al. (2006) use earnings forecasts while Bradley et al. (2008) use analyst recommendations and focus on the underwriter analysts only.

Michaely and Womack (1999) and Barber et al. (2007) observe that the IPOs with 'buy' recommendations from affiliated analyst underperform compared to those from independent ones. Their results seem to provide evidence in favor of the conflict of interest hypothesis. Similarly, James and Karceski (2006) note that favorable coverage is short-lived, disappearing on average by the 3rd analyst report written by lead underwriter analyst. They find that "booster shots" has a positive effect only in the first 30 days after IPO. McNichols et al. (2006), differentiating between short term and long term performance, observe that the market only discounts 'buy' recommendations from affiliated analysts within a three-day event window; they find no difference in performance between IPOs receiving affiliated and independent 'buy' ratings when the window is three-, six-, twelve-and twenty-four- month.

Ratings received appear to be correlated with IPO firm returns. Bradley et al. (2003), and Highfield, Lach and White (2008) find that firms that receive an average 'buy' outperform firms with an average 'hold'/'sell' rating. In addition, multiple 'buy' recommendations outperform a single 'buy' recommendation. Highfield et al (2008) present evidence that the number of 'buy' recommendations received up to three days after QPX positively influences firm returns over the one-, three-, six-, nine- and twelve-month period. 'Sell' and 'hold' recommendations exhibit no such pattern because they form only a small proportion of all recommendations. In addition, the average number of recommendations that firms received in the bear market is 2.72 (BJRW) which is higher than both the bull markets (1.72–BJR and 1.00–HLW). This suggests that analysts lend a helping hand to firms going public in a weak market by increasing the frequency of coverage.

In summary, the extant research has examined how the timing, attributes of analysts, and the ratings received affect IPO performance. There is hardly any study on how the

information content acts as a signal for the quality of the IPO that may influence the contemporaneous as well as the long term return of the IPO. This is the gap that we try to fill in this study.

3 Hypothesis Development

3.1 Information Content of Analyst Recommendations in the IPO Market

For this particular study, we examine analyst recommendations instead of earnings forecasts and growth rate projections for the following three reasons. Firstly, retail investors pay most attention and react strongest to recommendations because of the simple 'buy' or 'sell' message (Malmendier and Shanthikumar 2007). Secondly, we are interested in the value of equity analysts' recommendations to new public firms whereby the scarce historical data may render earnings estimates imprecise. Thirdly, recommendations represent "information content where the forecaster is recommending a clear and unequivocal course of action" (Elton et al. 1986). A 'buy' recommendation means that an analyst has analyzed all the available information and expects the stock to outperform.

Analysts function like "information capacitors" that discharge information when a critical amount of information is accumulated (as described in Charoenrook and Lewis, 2009). They rely on numerous sources of information (both public and private), including management of firms they cover, in forming their recommendations. It is possible that managers do not treat all analysts equally, instead favoring those who issue favorable recommendations (Chen and Matsumoto 2006). Such behavior would be consistent with research in experimental economics on "reciprocity". Analysts, however, have a duty to provide accurate information, no matter how strong the desire to please management. Therefore, we argue that analysts' strong incentives to provide accurate recommendations coupled with the motivation to gain management favor imply that the number of favorable recommendations should contain information about the favorableness of the IPO's prospects.

Bradley et al. (2003) introduce the "confirmation hypothesis" that total number of analyst recommendations has a significant positive relationship with the quiet period expiration ("QPX") returns. They argue that confirmation by different analysts is important to mitigate conflicts of interests and information asymmetry. When Highfield et al. (2008) extend the study from QPX to the post-IPO twelve months, they claim that it is the number of 'buy' recommendations, not the total number of recommendations that investors respond to.

We deduce from the above arguments that if analysts have the ability to identify long-run IPO winners and losers, and they select firms to issue 'buy' in which their true expectations are favorable, it follows that analysts' favorites - those with numerous 'buy' recommendations will contemporaneously exhibit superior returns. It follows that those with low proportion of 'buy' recommendations are not expected to perform well. We have hence, the following hypotheses.

H1A: IPO firms with high ratio of 'Buy' Recommendation to Total (BRT) outperform the market and matched firms.

H1B: IPO firms with low BRT ratio underperform the market and matched firms in the same holding period.

3.2   The Long-run Implications of Analyst Recommendations

Rajan and Servaes (1997) study the long-run implications of analysts' long-term earnings growth projections on IPO firms, using the first forecast made in the year following the IPO. They find strong evidence suggesting firstly, forecasts for IPOs are more optimistic than for seasoned firms. Secondly, there is a significant negative relation between the forecasts and long-run IPO returns. They attribute the IPO underperformance puzzle to analysts' over-optimism.

Dugar and Nathan (1995) , Lin and McNichols (1998) , Michaely and Womack (1999) and Dechow et al. (2000) among others document that analysts are overly optimistic around equity offerings with the affiliated analysts issuing more favorable stock recommendations and

more optimistic growth forecasts. Yi et al. (2008) report that the level of optimism in analyst

forecast increases within twelve months following equity issues.

We argue that in the market of relatively unknown new public firms, with analysts facing

various conflicts of interests and trying to gain favor with firm management, analysts'

recommendations in the first twelve months may be overly-optimistic with the subsequent

performance of such firms suffering. Thus we hypothesize that:

H1C: IPO firms with high BRT ratio in the first year of IPO underperform the market and

   matched firms in the subsequent two years.

3.3   Firms with Little or No Analyst Recommendation

Next, we are also interested in the group of IPO firms that receive little or no analyst

recommendations. The "differential information hypothesis" proposes the relationship between

firm neglect and small firm size effect. Elfakhani and Zaher (1998) find evidence that individual

investors could earn higher returns on stocks that receive scant coverage by financial analysts

in the 1986-1990 period. They attribute this to the "neglect-firm effect" where small firms

neglected by analysts' investors, financial analysts, and other investment agencies suffer from

the lack of public information and therefore, small uninformed investors require additional

returns as a risk premium for holding them. We posit that the level of recommendation proxies

for the firm neglect effect that result from analyst selectivity in coverage.

We hypothesize that the IPO firms with only one recommendation are neglect firms

because most analysts have dropped coverage on them. Therefore, we expect them to exhibit a

returns premium. As the majority of the single recommendations are 'buy', we further postulate

that these might be the "booster shots" that are pre-IPO committed. Many researchers report

empirical evidence that affiliated analysts' favorable coverage and "booster shots" are short-

lived with only positive effects in the first 30 days after IPOs (see James and Karceski 2006, and

Bradley, Chan, Kim and Singh 2008). Alternatively, it is logical that analyst drop coverage on

them because they predict them to be IPO losers not worthy of placing any effort to follow. The selective coverage behavior of analysts postulates that they rather drop coverage than to issue 'sell' recommendations when their true expectations on firms are unfavorable. Hence, we have the following hypotheses.

H2A: IPO firms with only one 'buy' recommendation are either neglected firms that exhibit positive returns premium vis-à-vis other firms, or firms that analysts deemed unworthy to follow and hence exhibit the worst underperformance vis-à-vis other firms.

H2B: IPO firms with "booster shots" should have no long-run implications on performance.

We also note that there are IPO firms with zero analyst recommendation and wish to investigate why analysts are silent on these firms. One possibility is that they are neglect firms as well. Alternatively, analysts deem them unworthy to follow. Analysts face multiple conflicting incentives which are further aggravated by their limited resources and the huge pool of stocks to follow in the capital markets. Their decision to initiate coverage and follow a stock is thus not a random act. Anecdotal reports are also consistent with the notion that analysts' underlying expectation is a potential determinant in recommending newly public firms: "The burgeoning IPO market makes it tough for analysts to follow every deal. …With so many deals coming through, at some point analysts have to pick and choose, and they are going to choose the companies with great long-term prospects. That is how their firms make money" (Finegan, Useem and Mamis 1996). Our final hypothesis is:

H3: IPO firms with no recommendation are either neglected firms that exhibit positive returns premium vis-à-vis other firms, or firms that analysts deemed unworthy to follow and hence exhibit the worst underperformance vis-à-vis other firms.

4   Methodology

4.1 Variables

Table 1 shows the proxies for the variables used in this study. Our study requires the computation of abnormal buy-and-hold returns for multiple post-IPO holding periods T = 12, 24 and 36 months. Two returns measures are used: buy-and-hold returns in excess of the market (VWBHAR), and buy-and-hold returns in excess of matched firms (MFBHAR). The strength of analysts' recommendation is computed by "Buy Relative to Total Recommendations" (BRT). Using the BRT ratio instead of the raw number of 'buy' recommendations normalizes the recommendation index to allow comparison among firms. Ceteris paribus, the higher the BRT, the more highly recommended the firm is by analysts. BRT takes on the highest value of one when all recommendations are 'buy'.

———————————————

INSERT TABLE 1 ABOUT HERE

———————————————

Excluding the firms with one 'buy' and zero recommendations, we further segregate the firms into three groups (low, medium and high) based on BRT. Our second and third main variables of interest are dummy variables Dum_HighBRT and Dum_LowBRT with values equal to one when firms fall into the respective High BRT and Low BRT groups and zero otherwise. In addition, we create the third dummy variable Dum_OneBuy, to represent firms with only one 'buy' recommendation within period T. Since firms with only one 'buy' recommendation will have BRT equal to one, they might be mistaken for "analysts' darlings". Dum_OneBuy controls for that. In addition, we posit that these single buy recommendations may be "booster shots" that are pre-IPO committed. Dum_ZeroRec is a dummy variable for firms with zero recommendation within period T.

Twelve control variables are included in our study. The first control variable is the number of analysts providing recommendations for a firm for period T (NumAna). The second control variable is the divergence of analysts' recommendations (Divergence). It is the standard

93

deviation of the analysts' recommendations for period T published in I/B/E/S. A high value of Divergence signifies that the recommendation is made in a "noisy" environment with greater divergence from the consensus recommendation. Firms with values of Dum_OneBuy or Dum_ZeroRec equals to one will have Divergence equals to zero. The third control factor is the initial returns of the IPO firms (InitialR). It is the return between the IPO price and the first aftermarket closing price listed on CRSP. This represents what investors will earn by buying the IPO shares at the offer price and selling them at the end of the first trading day. The fourth control factor is a dummy variable for venture-capital backing (Dum_VC). The fifth control factor is the age of the firm at the time of IPO (Age). The sixth control factor is a dummy variable for NASDAQ listing (Dum_NASDAQ). The seventh control factor is the capital asset pricing model ("CAPM") beta relative to the CRSP Value-Weighted Index and Fama risk free rate (Beta). This is to proxy for the market risk in the Fama and French three factor model. Their measure is an ex-ante beta and since it is impossible to calculate ex-ante beta for IPO firms as they do not have share prices prior to listing, we calculate ex-post beta. The eighth control factor is the size of the firm (Size). The ninth control factor is the book-to-market value (BMV). We compute MCAP and BV at the first month-end of IPO for matching firm purposes. The tenth control factor is the annual IPO volume (IPOVol). The eleventh control factor is dummy variable to represent firms that are delisted within 36 months of the IPO (Dum_Delisted). The final set of control factors are the 17 dummy variables that represent the industry sectors grouped by NAICS ($DumInd_k$).

4.2   Data

A list of all the firms that completed their initial public offerings in the U.S. and subsequently listed on the Center for Research in Security Prices ("CRSP") is obtained from Ritter's website (Ritter, 2008). This dataset (updated in 2008) contains the names and CRSP permanent IDs ("PERMNO") of the firms that went public between 1975 and 2008. For data on

IPO firm characteristics, we download the entire New Issues dataset in Securities Data Corporation ("SDC"). Data pertaining to returns, prices, number of outstanding shares and the like are retrieved from CRSP.

Our original sample contains 4,287 firms that went public in 1994-2006[6] period. We drop firms that are de-listed, American Depositary Receipts (ADRs), IPO firms with offer price less than $3, firms that have their first-day closing price listed on CRSP more than three calendar days from the offer date, firms with insufficient data to compute returns and those with negative book values from our study. Our final sample consists of 3,596 firms (for 12-month holding *period)*, 3,116 firms (for 24-month holding period) and 2,167 firms (for 36-month holding period) that completed their IPOs between January 1994 and December 2006. Firms that completed their IPOs in 2006 are analyzed using the 12 and 24-month holding period returns only.

We obtain the IPO offer price, firm founding year, venture-capital backing and total proceeds (including oversold) for the entire U.S. IPO market from SDC New Issues dataset. Stock returns, monthly closing prices and number of outstanding shares are retrieved from CRSP - Returns + Decile Assignments database with the event time window starting from the IPO offer date ending 36 months later. Book values, exchange listing and NAICS industry classification are retrieved from CRSP/COMPUSTAT Merged Database - Price, Dividends, and Earnings (Annual Format) database.

The following procedure is employed to select matched firms for our sample IPO firms. For each IPO firm, we first compute its MCAP and BMV at the first calendar month-end of the IPO offer date, which is the reference point for matching[7]. To find a matching firm within the

---

[6] The sample period of 1994–2006 is chosen to maximize the availability of analyst recommendations on I/B/E/S *(data availability: Oct 1993-Mar 2008)*. As Bradley et al. (2003) noted, we do recognize that I/B/E/S coverage may be less complete in the beginning years of our sample period, resulting in the possibility of labeling some firms as having received no analyst recommendations when, in fact, they did.

[7] However, due to issues like missing data and negative book values, some IPO firms cannot be matched immediately at the first month-end of IPO. We look to the next month-end for data. Our sample IPO firms are

same industry as the IPO firm, we compute the MCAP and BMV available from the CRSP monthly database for each non-IPO firm at the same calendar month-end. From all the non-IPO firms with MCAP value that is from 80% to 120% that of the IPO's MCAP, we select the one with the closest BMV as the matched firm. If a matching firm is not available, a small firm within the same industry is selected to avoid the small firm effect that Ritter (2006) finds in IPO underperformance. In more than 800 of our 3,596 IPO firms, the original matching firms are de-listed within 36 months following the IPO date. Therefore, we select the next best matching firm that provides sufficient data to compute the matched firm buy-and-hold returns. In sum, our sample IPO firms are matched to non-IPO firms within the same industry on the basis of similar MCAP and BMV.

Data on analyst recommendations is obtained from Thomson Financial Institutional Brokers Estimate System ("I/B/E/S") through the Wharton Research Data Services ("WRDS"). I/B/E/S maintains a standard set of recommendations on a five-point rating scale, where '1' represents 'strong buy', '2' represents 'buy', '3' represents 'hold', '4' represents 'underperform' and '5' represents 'sell'. We convert the data to a three-point scale in which 'buy': rating of '+1' *(equivalent to 'strong buy' and 'buy' in I/B/E/S)*, 'hold': rating of '0' (equivalent to 'hold' in I/B/E/S) and 'sell': rating of '-1' *(equivalent to 'underperform' and 'sell' in I/B/E/S)*. We also utilize the I/B/E/S Recommendations - Summary Statistics (Consensus Recommendations)[8] file for the monthly market consensus recommendation.

4.3 Model

In this study, we propose two models to test our hypotheses. One is a contemporaneous model and the other, a lead lag model to examine the long term performance. The contemporaneous model has the following equation.

---

matched within the first six months after their IPO, based on the first available MCAP and BMV values.
[8] I/B/E/S publishes a monthly consensus based on the average recommendation rating for each stock.

$MFBHAR_{iT}$ = α + $\beta_1 Dum\_HighBRT_{iT}$ + $\beta_2 Dum\_LowBRT_{iT}$ + $\beta_3 Dum\_OneBuy_{iT}$ +

$$\beta_4 Dum\_ZeroRec_{iT} + \sum_{i=5}^{32}(V_{iT}) \tag{1}$$

Where T = 12, 24 and 36; and V_{iT} are the control variables given in Table 1.

This model, also analyzed with $VWBHART_{iT}$ as the dependent variable, examines the contemporaneous relationship between the abnormal performance of IPO firms and the favorableness of analysts' recommendations. Excluding those firms with zero and single recommendation, we assign the remaining firms into low, medium and high *BRT* groups according to the scale[9] below for each holding period under study. Table 2 summarizes the number of firms within each *BRT* group, together with those that has zero or one recommendation within the three holding periods. Table 2 shows that the number of firms with one hold or sell recommendation within period *T* to be small. Since no meaningful tests can be conducted with such a small sample size, these will not be included in our model.

_____

INSERT TABLE 2 ABOUT HERE

_____

If analysts' recommendations are indeed accurate about the contemporaneous IPO performance, we expect firms with high (low) *BRT* to outperform (underperform) the market and matched firms. That is, the coefficient (β_1) for *Dum_HighBRT$_T$* is positive, indicating superior performance vis-à-vis the market and matched firms; while the coefficient (β_2) for *Dum_LowBRT$_T$* is negative. As for the firms with one 'buy' and no recommendations, we postulate that since analysts either drop coverage or do not even initiate coverage on them, they may be neglected firms that will exhibit a returns premium. Alternatively, they may be the firms that analysts predict to be long-run IPO losers – the lemons that exhibit the worst performance of all firms. The expected signs of the coefficients from our hypotheses are:

_____

[9] The cut-off score for the BRT groups is derived from the 36-month sample with the aim of attaining three equal-sized groups of firms with at the best possible.

97

H2B: $\beta_1 > 0, \beta_2 < 0$; H3A: $\beta_3 = 0$ (null); H4: $\beta_4 = 0$ (null)

The above models will provide the models for testing the relationship between analyst recommendations and contemporaneous returns. To investigate the long-run implications of analysts' recommendations, we propose a lead-lag model to isolate the returns for the time period following the recommendations. The lead variable is the *BRT* ratio in the first twelve months, while the lag variable is the *MFBHAR* in the next twelve to twenty-four months. The equation for the model is shown below.

$$MFBHAR_{iT} = \alpha + \beta_1 Dum\_HighBRT_{12} + \beta_2 Dum\_LowBRT_{12} + \beta_3 Dum\_OneBuy_{12} +$$
$$\beta_4 Dum\_ZeroRec_{12} + \sum_{i=5}^{32}(V_{iT}) \tag{2}$$

where $T = 13\text{-}24$ and $13\text{-}36$; and V_{iT} are the control variables given in Table 1.

We also run our regression using $VWBHART_{iT}$ as dependent variable. We hypothesize that analysts are over-optimistic in recommending newly public firms in the first year of their IPO. Those firms that are highly recommended by analysts will underperform the market and matched firms in the subsequent two years. We also hypothesize that firms with one 'buy' recommendation are firms which received a "booster shot" that is pre-IPO committed should not have any implications on the long-run performance. In a nutshell, we hypothesize that:

H1B: $\beta_1 < 0$; H2B: $\beta_3 = 0$ (null); H3: $\beta_4 = 0$ (null)

5 Data Analysis and Discussion

5.1 Descriptive Data

Our sample comprises of 83.9% of the total IPO firms in the U.S. market during the 1994-2006 period. Table 3 presents descriptive statistics for the sample data. Panel A describes the IPO firm characteristics. An investor buying shares at the IPO price and selling at the end of the first trading day enjoys returns of 18.84%. This positive initial returns ("InitialR") is consistent with the (short-run) under-pricing anomaly documented in the literature that the

majority of IPOs see a jump in their stock price on the first trading day. This value is close to the 18.80% reported in Ritter and Welch (2002)[10]. The mean age[11] of the firms at the time of IPO is 15.45 years. Venture capitalists back 39.74% of the IPOs in this study. Approximately 83% of the firms are listed on the NASDAQ. By the ex-post measure of the capital asset pricing model ("CAPM") beta, our IPO firms are more risky than the market with a mean beta of 1.634. Loughran and Ritter (1995) also find that the beta is higher for IPO firms than for non-IPO firms. They argue that these firms should therefore have higher, not lower long-run returns. The mean market capitalization ("MCAP") and book-to-market value ("BMV") of our IPO firms are $586,840 and 1.7537 respectively, measured at the first month-end of the IPO[12].

_____

INSERT TABLE 3 ABOUT HERE

_____

Panel B describes the strength of analyst recommendation for holding periods of 12, 24 and 36 months. In this study, the classification of analyst recommendations is on a three-point scale of 'buy' (favorable), 'hold' (neutral) and 'sell' (unfavorable). Our sample of 3,596 IPO firms is reduced to 3,118 (24 months) and 2,171 (36 months) with firms being delisted over time. In the first year of IPO, 73.79% of the recommendations received by the firms are a 'buy' rating ("*BRT*"), 14.67% are 'hold' ("*HRT*") and 1.03% are 'sell' ("*SRT*"). 10.51% of the firms are not covered by any analysts. On average, each firm is covered by four analysts who provide recommendations with the mean divergence (standard deviation of recommendations) of 0.4238. The number of analysts increases to approximately eight with a mean divergence of 0.5239 for the three-year holding period. While *BRT* decreases to 66.81% for the three year holding period,

---

[10] Authors provide a review of the IPO activity, pricing and allocations in the U.S. market for the period 1980-2001.
[11] Age is measured by the natural logarithm of one plus the difference between the IPO and the founding year.
[12] These values are computed when we match our sample IPO firms to control (non-IPO) firms.

HRT and *SRT* increase to 24.09% and 2.43% respectively. The proportion of firms not covered decreases to 6.69% as well. Over the three years, even though *BRT* declines, it is still much higher than *HRT* and *SRT*. This is consistent with the literature that analyst recommendations are typically favorable (see Bradley et al. 2003)[13].

We also analyzed but not shown here the changes in recommendation changes over time. The total number of recommendations for IPO firms decreases by 47.3% from 22,207 in the IPO year to 11,703 by the third year. The total number of 'buy' recommendations sees an even greater decline of 59.79% from 17,283 to 6,949 by the third year even though the sample size decreases by only 39.7% 3,596 firms to 2,167 firms. These findings provide evidence that analysts revise their expectations on IPO firms downwards after the first year of IPO.

Panel C displays the Pearson correlation matrix of the variables. Even though all the correlations are significant, the correlation between the variables is generally low with the exception of the correlation between 1) BRT_{12} and $ZeroRec_{12}$ ($\rho=-0.8003$) which is expected since they are mutually exclusive, 2) $Size_{12}$ and $NumAna_{12}$ ($\rho=0.6710$), consistent with the fact that larger firms attract more analysts following and 3) BHR_{13-24} and BHR_{13-36} ($\rho=0.6447$) which contains overlapping data. We find a positive relation between the number of analysts providing recommendations and the firm size, initial returns, beta, venture-capital backing and annual IPO volume. These observations, similar to that of Pearson (1992) and Rajan and Servaes (1997), indicates attributes of IPOs that spark analyst interest in following IPO firms.

5.2 Multivariate Analysis

We run the GMM regressions given in equations (1) and (2) to examine the relationship between analyst recommendations and IPO performance. Running this regression allows us to control for joint effects and correct for heteroskedasticity.

---

[13] Authors examine 1,611 IPOs from 1996-2000. They find about 96% of all recommendations are either 'strong buy' or ''buy'' (63% are ''buy''). Out of 2,747 recommendations, there is only one rating of 'hold' and not a single 'sell'.

Table 4 presents the results for the contemporaneous model using $MFBHAR_T$ and

$VWBHAR_T$ as dependent variables. The adjusted R^2 values are in the range of 21.90% to

52.12%, signifying a relatively strong explanatory power. Hypothesis H1A suggests that the

coefficient estimate on Dum_HighBRT_T will be positive ($\beta_1>0$). The regression results support

this hypothesis in every holding period showing that IPOs with high proportion of 'buy'

recommendation have higher contemporaneous returns compared to the market returns and

matched firms. It is clear that for the contemporaneous case, IPOs with high analyst ratings

outperform the market and matched firms. Our hypothesis in H1B suggests that the coefficient

of Dum_LowBRT$_T$ ($\beta_2<0$) will be negative. We find strong results in favor of this. IPOs with

relatively low proportion of 'buy' ratings do worse compared to the market and matched firms.

There is thus, some evidence that the analyst information accurately predicts the returns

outcome for the IPOs in the short term. H2A suggests that since we apriori have conflicting

reasons why the IPOs have only one recommendation, we expect the coefficient of

Dum_OneBuy_T equals to zero ($\beta_3=0$). The results, however, strongly show that IPOs with one

'buy' recommendation outperforms the matched firms and the market over the 12- and 24-

month holding periods. It thus appears that these IPOs are exhibiting the neglect-firm effect that

provides the risk premium to investors to account for the lack of information. For hypothesis H3,

we expect the coefficient of $Dum\_ZeroRec_T$ to be equal to zero ($\beta_4=0$). The results show that β_4

is significantly greater than zero providing compelling evidence that firms which receive zero

recommendations are neglected firms that with higher returns to justify the risk of holding them.

We thus find compelling evidence of the neglect-firm effect for two classes of IPOs: those with

only one 'buy' recommendation and those with zero recommendation. Overall, the results of our

contemporaneous model in Table 4 support H1A, H1B and clarify the direction of H2A and H3.

_____

INSERT TABLE 4 ABOUT HERE

_____

Table 5 presents the results of the lead-lag model used to test our hypothesis on the long term effect of analysts' recommendations. The dependent variables are the one-year abnormal holding period return in the second year after IPO and the two-year abnormal holding period return spanning the second and third year after IPO. The returns of the IPOs are compared with matched firms ($MFBHAR_T$) and the market ($VWBHAR_T$). The adjusted R^2 values are in the range of 3.71% to 34.80%. Our hypothesis in H1C suggests that the coefficient of $Dum\_HighBRT_T$ should be negative ($\beta_1<0$). The results strongly support this hypothesis that IPOs with high percentage of 'buy' ratings underperform matched firms and the market over the long term. It appears that the analyst recommendation for these IPOs may initially be over-optimistic resulting in overvaluation which causes subsequent reversion to its fundamental value. From H2B, we expect the coefficient of Dum_OneBuy_T to be equal to zero ($\beta_3 = 0$) as we expect these to be one-time booster shots with no long term performance implications.   Here, we are unable to reject the null hypothesis for the second year returns (13-24 months). This indicates that firms with one 'buy' recommendations in the first year of IPO significantly underperform the market and matched firms in the following year, concurrent with the period that usually sees the most severe IPO underperformance. Such "booster shots" however has no implications over the two year holding period (13-36 months), where our hypothesis H2B is supported. Our last hypothesis H3 posits that IPO firms with zero coverage are either neglected firms that exhibit positive returns premium vis-à-vis other firms, or firms that analysts deemed unworthy to follow and hence exhibit the worst underperformance vis-à-vis other firms. Our results show that the coefficient of $Dum\_ZeroRec_T$ is significantly negative for matched firms and the market for the second year returns and for the market for the third year returns. Taken together with the positive results for the contemporaneous model in Table 4, we thus gather that investors may have initially overpaid for IPO firms with no recommendations, resulting in long term underperformance. Overall, the result in our lead-lag model support H1C, reject H2B and tilts

our understanding of H3 towards the view that firms with no recommendation are overpriced after the first year.

H1A, H1B and H1C relates the proportion of 'buy' recommendation to IPO firms' returns performance relative to matched firms and the market in order to investigate the information content in analysts' 'buy' recommendations. Our results find significant support for H1A and H1B that IPO firms with more recommendations perform better contemporaneously while those with lower proportion perform worse. However, we find from H1C that over the long term, firms with greater proportion of 'buy' recommendation perform worse that matched firms and market. We thus can conclude that while contemporaneous information from the analysts tracks the IPO performance, the same information is not relevant for the long term. Analysts' over-optimism in new public firms may account for this observation. Research analysts are confronted with conflicts of interests that might adversely affect their objectivity. The "Global Research Analyst Settlement" with twelve major investment banks in 2001 has uncovered bias in analysts' coverage. Beyond biased coverage, analysts may not possess superior information about new public firms compared to the market. Since the decision to choose underwriters for IPO firms has always been heavily influenced by the quality and extent of aftermarket research coverage that they can provide, IPO firms will gravitate towards underwriting firms that can provide favorable recommendations that may not necessarily add substantial long-run shareholder value. Thus, investors may bid up the prices of such firms above their fundamental value when analysts are "hot" about them, and drive down the prices down to their fundamental when the realization that the firms are overvalued hits. It is thus, not unreasonable to ascribe long-run IPO underperformance to analysts' over-optimism.

What about IPO firms that are neglected by analysts. Our results pertaining to Hypotheses H2A and H3 finds that IPO firms with one or zero recommendations behave like neglected firms in the short term and show positive abnormal returns to account for the risk compared to matched firms and the market. Over the long term, these IPO firms fail to

outperform and in many instances underperform compared to matched firms and the market. The outcome these firms face is thus similar to firms that encounter analyst over-optimism – positive abnormal contemporaneous returns and negative long term abnormal returns. We however, cannot reject the possibility that analysts are able to identify the long-run IPO losers and they choose not to follow them right from the beginning of the IPO.

6   Conclusion, Limitations and Future Research

The long-run underperformance of IPO firms is a well-documented anomaly in the literature. In this paper, we try to understand the underperformance puzzle by looking at analyst recommendations. We examine 3,596 firms that completed their IPOs in the U.S. market during the period of 1994-2006. This study presents five key findings. First, we find evidence that analysts can collectively inform the market accurately about the contemporaneous performance of IPO firms through the proportion of 'buy' recommendations. There exists a significant positive relationship between the proportion of 'buy' recommendations and the contemporaneous abnormal returns of IPO firms. Second, we find that firms that are ascribed a low proportion of 'buy' recommendations significantly *underperform* matched firms in the contemporaneous period. Our results suggest that the interaction between analyst recommendations and firm resultant firm performance is dynamic and complex. In such an information environment where a "feedback loop" between analyst and the IPO firm may exist through the practice of "earnings guidance", analyst recommendations appear to contain information about the true prospects of firms.

Third, our study provides information about the implications of analyst recommendations on IPOs for buy-and-hold investors. Our results indicate that for an investor who buys the shares of "analysts' darlings" that contemporaneously exhibit superior outperformance at the end of the first year, and holds them for the next two years, will find that their investments will significantly underperform the market and matched firms. Consistent with the literature, our

104

results suggest that analysts might be overly-optimistic in recommending 'buy' for some IPO firms in the initial year of listing. The "analysts' darlings" turned out to be a disappointment for the buy-and-hold investors, just like how the highly recommended stocks turned out to be disasters during the technology bubble.

Fourth, this study finds compelling evidence of the neglect-firm effect in IPO firms with little or no analyst coverage. Such firms earn significant contemporaneous returns premium but underperform in the long run. Traditionally, the neglect-firm effect has been attributed to the small size of the firm. Even though our sample firms with no coverage are indeed smaller firms, we argue that the lack of analyst coverage, professional analysis and information flow to the market about such new public firms result in uninformed investors demanding higher expected returns. This is consistent with our findings that that the number of analyst providing recommendations and the level of divergence in recommendations inversely impact the long-run performance of IPO firms. Fifthly, we find that the neglected firms with one 'buy' or with zero recommendations underperform the market and matched firms over the long term. It is possible that the investors have chased the price of these IPOs up too high in the first year and the underperformance in the second and third year reflects the price aligning with the fundamental values of the firms.

A limitation of this research is the lack of data on analyst recommendations, thus restricting our study to a period of thirteen years. If reliable data could be retrieved for a longer sample period, we could provide results that can be more generalizable. In addition, if the characteristics of the individual analysts providing recommendations for the IPO firms are collected, a richer and more insightful analysis can be obtained.

The following areas are potential areas for further research. The literature suggests that issuers value analyst coverage and willingly under-price issues to "purchase" favorable coverage. Therefore, the relation of under-pricing and how it attracts analysts following, and the resulting implications on the long-run performance can be examined concurrently in greater

extent. In addition, the "hot" market issue is another interesting area to explore in terms of whether market conditions itself has an effect on long run underperformance.

Table 1 Variables Used in the Study

Variables	Notation	Formula	Remarks
Matched Firm Adjusted Buy-and-Hold Abnormal Returns	MFBHAR_{iT}	$$\prod_{t=1}^{T}(1+R_{iT})-\prod_{t=1}^{T}(1+R_{jT})$$	R_{jT} is the dividend-adjusted return for (non-IPO) size, book-to-market and industry matched firm T = 12, 24, 36
Value Weighted Market Adjusted Buy-and-Hold Abnormal Returns	VWBHAR_{iT}	$$\prod_{t=1}^{T}(1+R_{iT})-\prod_{t=1}^{T}(1+R_{mT})$$	R_{mT} is the monthly market returns T = 12, 24, 36
Buy Relative to Total Recommendations	BRT_{iT}	$$\frac{No.of\ Buy\ \mathrm{Re}commendations\ within\ period\ T}{Total\ No.of\ Buy\ \mathrm{Re}commendations\ within\ period\ T}$$	T = 12, 24, 36
High BRT	Dum_HighBRT_{iT}	Dummy Variable = 1 if firm i is classified into the high BRT group within period T and 0 otherwise	-
Low BRT	Dum_LowBRT_{iT}	Dummy Variable = 1 if firm i is classified into the low BRT group within period T and 0 otherwise	-
One Buy Recommendation	Dum_OneBuy_{iT}	Dummy Variable = 1 if there is one recommendations and it is a 'buy'for firm i within period T and 0 otherwise	-
Zero Recommendation	Dum_ZeroRec_{iT}	Dummy Variable = 1 if there are zero for firm i within period T and 0 otherwise	-
Number of Analysts	NumAna_{iT}	Number of analysts providing recommendations for firm i within period T	-
Divergence of Recommendations	Divergence_{iT}	$$\sqrt{\frac{\sum(\mathrm{Re}c-\mathrm{Re}c_{average}}{N}}$$	Standard deviation of the analysts' recommendations
Initial Returns	InitialR_{i}	$$\frac{First\ Day\ Clo\sin g\ \mathrm{Pr}ice-IPO\ Issue\ \mathrm{Pr}ice}{IPO\ Issue\ \mathrm{Pr}ice}$$	-
Venture Capital Backed	DumVC_{i}	Dummy Variable = 1 if the IPO is backed by venture-capital and 0 otherwise	-

Table 1 Variables Used in the Study (continued)

Variables	Notation	Formula	Remarks
Firm AGE	Age_i	Ln [1 + (Year of IPO – Year of Founding)]	Age of firm at the time of IPO
NASDAQ Listing	Dum_NASDAQ_{iT}	Dummy Variable = 1 if firm i is trading on NASDAQ at time T and 0 otherwise	-
CAPM Beta	$Beta_i$	Slope of regression of $$\sum_{t=1}^{T}(R_{it} - R_{ft})\ on\ \sum_{t=1}^{T}(R_{mt} - R_{ft})$$	R_{it} is the dividend-adjusted return for (IPO) firm i in month t, R_{mt} is the return of CRSP Value-Weighted Index and R_{ft} is the Fama 1-month risk free rate in month t
Firm Size	$Size_{iT}$	$Ln(MCAP_{iT})$ $MCAP_T$ = Number of shares outstanding x closing price on the last trading day of period T	Market value of IPO firm
Book-to-Market Value	BMV_{iT}	$$\frac{Book\,Value_{iT}}{MCAP_{iT}}$$	Book value is observed at the last fiscal year end within period T
Annual IPO Volume	$IPOVol_T$	ln (Total IPO proceeds including oversold in the calendar year of IPO)	-
Delisted Firms	$(Dum_{Delisted})_i$	Dummy Variable = 1 if firm i is delisted within 36 months after IPO and 0 otherwise	-
Industry	$(DumInd_k)_i$	Dummy Variable = 1 if firm i falls within the industry sector denoted by k and 0 otherwise	-

Table 2 Distribution of Recommendations Over Multiple Holding Period

T	N	Zero Rec	One Hold/ Sell	One Buy	Low BRT	Medium BRT	High BRT
					0 =< BRT <= 0.625	0.625 < BRT <= 0.8	0.8 < BRT <= 1
12	3,596	378	15	171	564	695	1,773
24	3,118	236	11	73	794	888	1,116
36	2,167	145	5	31	648	714	624

Table 3 Descriptive Statistics of Sample

BRT, HRT and *SRT* represent the ratio of buy, hold and sell relative to the total number for recommendations within period T respectively.

N represents the number of observations.

***, **, * signify if the estimate is statistically significant at the 1%, 5% and 10% levels respectively.

DO DIGITAL REPORTING FORMATS IMPACT DECISION ACCURACY AND COGNITIVE EFFORT?

Erlane K. Ghani, *Universiti Teknologi Mara, Malaysia*
Fawzi Laswad, *Massey University, New Zealand*
Stuart Tooley, *Queensland University of Technology, Australia*

Abstract

This study examines the impact of digital reporting formats (HTML, PDF, and XBRL) on decision accuracy and cognitive effort in an accounting context. Using an experimental design involving professional accountants as participants, the results indicate that digital reporting formats impact decision accuracy. Participants who used XBRL achieved higher accuracy than participants who used PDF but no significant differences were found between the use of XBRL and HTML, and HTML and PDF. These results support the notion in the psychology literature that different forms of reporting make some aspects of the information displayed more apparent. There were no significant differences in cognitive effort between the three digital reporting formats. The findings are of interest to organizations that publish financial reports and regulatory bodies that require financial reports be made publicly in digital formats.

1. Introduction

This paper examines whether digital reporting formats impact decision-makers' performance in relation to improving accuracy and minimizing cognitive effort. Several factors influence decision quality such as decision-makers' characteristics, task features, information content and the environment within which the decision is made (Libby and Lewis 1977, 1982; Maines 1995; Roberts 2002). Libby and Lewis (1982) and Maines (1995) suggest that using appropriate presentation formats improves decision quality as presentation formats improve decision quality and overcome the limited ability of humans to process a large quantity of data. The findings of various studies support this notion (Rohrman, 1986; Bricker and Nehmer, 1995; Ramarapu et al., 1997; Frownfelter-Lohrke, 1998; Hodge, 2001; Dull et al., 2003; Hodge et al., 2004).

Abdolmohammadi et al. (2002) suggest there is a need to examine the impact of digital reporting formats on decision-makers' decision quality. Baldwin et al. (2004) suggest the need to examine the impact of XBRL in enhancing decision-makers' performance since the main objective of the preparation of corporate reports is to provide transparency of financial reporting.

This paper uses an experimental design to examine the impact of digital reporting formats (PDF, HTML, and XBRL) on decision accuracy and cognitive effort in the

context of using accounting reports in an investment decision. The results support the notion that digital reporting formats impact on decision accuracy but not cognitive effort. As financial reporting is moving to the digital environment and as the US Securities and Exchange Commission has adopted XBRL as the standard for financial reporting, this study contributes to the understanding of the link between digital reporting formats and decision quality. The findings will assist preparers in selecting appropriate reporting formats in disseminating information to users of such reports.

The remainder of this paper is structured as follows. The next section provides a literature review of reporting and presentation formats and their impact on decision quality. Section 3 discusses the research framework and hypotheses. Section 4 outlines the research method. The results are presented in Section 5. A summary and conclusion is provided in the last section.

2. Literature Review

Various studies have examined the effect of traditional reporting (e.g., tabular versus graphical) formats on decision-makers' performance (Stock and Watson, 1984; Hard and Vanecek, 1991; Vessey, 1991; Vessey and Galletta ,1991; Umanath and Vessey, 1994; Frownfelter-Lohrke, 1998; Speier et al., 2003). Other studies have included formats from linguistic and numerical (Stone and Schkade, 1991), multimedia versus hardcopy (Clements and Wolfe, 1998, 2000; Rose 2002), bullet point and graph (Almer et al., 2003), to digital reporting formats such as Portable Document Format (PDF), Hypertext Mark-up Language (HTML) and Extensible Business Reporting Language (XBRL) (Hodge, 2001; Dull et al., 2003; Hodge et al., 2004).

Brown and Eining (1996) suggest that presentation formats have a behavioural impact on decision-makers' learning, strategy selection, decision quality and experience of satisfaction. Kleinmuntz and Schkade (1993) propose two cost-benefit dimensions of decision quality: accuracy and cognitive cost. Decision accuracy reflects the ability of a strategy to produce an accurate outcome (Ashton, 1991). Cognitive effort refers to the total expenditure of cognitive resources required to complete a task (Frownfelter-Lohrke, 1998) Accuracy is assessed by comparing the decision outcome with a relevant benchmark while cognitive effort is assessed by the amount of time needed to complete the decision task. Various studies have examined these two dimensions of decision quality (such as Hard and Vanecek, 1991; Ramarapu et al., 1997; Frownfelter-Lohrke, 1998; Dull et al., 2003).

Many studies suggest the use of appropriate digital and non-digital reporting formats increases decision accuracy (Stock and Watson, 1984; Dickson et al., 1986; Iselin, 1988; Vessey, 1991; Mackay and Villareal, 1987; Hard and Vanecek, 1991; Stone and Schkade, 1991; Anderson and Kaplan, 1992; Ramarapu et al., 1997; Frownfelter-Lohrke, 1998; Almer et al., 2003; Bizarro and Baldwin, 2004; Hodge et

al., 2004). Further, decision-makers experience a reduction in decision accuracy and higher cognitive costs in completing tasks where inappropriate presentation formats are used (Vessey, 1991; Vessey and Galletta, 1991; Umanath and Vessey, 1994; Speier et al., 2003). However, some studies suggest that presentation formats do not affect decision accuracy (Bricker and Nehmer, 1995; Dull et al. 2003; So and Smith 2003). These studies suggest that the degree of information processed as well as the type of tasks performed impact the effectiveness of reporting formats in improving decision accuracy.

The link between decision accuracy and presentation formats is attributed to factors such as matching of presentation format and task (Vessey, 1991; Umanath and Vessey, 1994) and the idiosyncrasies of presentation formats (Moriarity, 1979; Hard and Vanecek, 1991; Frownfelter-Lohrke, 1998).

Some studies have suggested that using appropriate reporting formats reduces cognitive effort in the decision-making task (Schwartz and Howell, 1985; Jarvenpaa, 1989; Vessey, 1991; Coury and Bouletter, 1992; Stone and Sckhade, 1991, 1994; Bricker and Nehmer, 1995; Tuttle and Kershaw, 1998). However, other studies have found that presentation formats do not affect cognitive effort (Benbasat and Dexter, 1985; Dickson et al., 1986; Jarvenpaa, 1989; Wilson and Zigurs, 1999; Dull et al., 2003).

The diverse findings in the literature that link cognitive effort with presentation formats could be attributed to factors such as the size of tasks (Dull et al. 2003), cognitive style (Bizarro and Baldwin, 2004), the degree of processing (Bricker and Nehmer, 1995), experience (Sabherwal and Grover, 1989), gender (Almer et al., 2003), and familiarity with reporting formats (Taylor and Brownfield 2002). These studies incorporate diverse research settings and tasks, including financial forecasting and time series information (Carbone and Gorr, 1985; DeSanctis and Jarvenpaa, 1989; Bouwman et al., 1995), cash flow prediction (Goldwater and Forgarty, 1995), investment decision (Dull et al., 2003; Hodge et al., 2004), retrieval task (Almer et al., 2003; Bizarro and Baldwin, 2004), and word usage (Nouri and Douglas Clinton, 2006).

The mixed results could also be attributed to sample selection. Most of the studies in the reporting format literature (for example; Hard and Vanecek, 1991; Ramarapu et al., 1997; Dull et al., 2003) examine the effect of reporting format on decision quality using a sample of students as proxy for investors. Although a recent study by Elliot et al. (2004) indicates that students may have similar characteristics to investors, other studies have shown that students' experiences and beliefs are different to those of investors (Bouwman et al., 1995; Hunton and McEwen, 1997; Vera-Munoz et al., 2002). Hence, it could be argued that it is difficult to generalise the findings from these studies as the research subjects may not represent actual decision-makers.

3. Hypotheses

Figure 1 illustrates a model showing the effect of reporting format on decision quality. The model is based on Libby and Lewis' (1977) and Brown and Eining's (1996) classification of variables affecting decision quality. This model suggests that reporting formats impact decision accuracy and cognitive effort. This impact is confounded by decision-makers' characteristics, experience and familiarity with reporting formats.

<Insert Figure 1 Here>

This study extends Hodge et al.'s (2004) study by examining the impact of three reporting formats: Portable Document Format (PDF), Hypertext Mark-up Language (HTML) and Extensible Business Reporting Language (XBRL) on decision quality.

Hodge et al. (2004) examined and compared two reporting formats in the digital reporting environment. They compared searchable (XBRL) and non-searchable (PDF) reporting formats and examined the effectiveness of the two reporting formats in assisting users to acquire and integrate information on stock option compensation. They found that XBRL provided more transparency of information presented in footnotes and consequently, the participants who used XBRL obtained higher accuracy in making investment decisions. PDF, on the other hand, provided information in sequential order making the information less transparent.

Bosak and Bray (1999) and Abdolmohammadi et al. (2002) distinguish between the three digital reporting formats (PDF, HTML and XBRL) according to their information processing features. They describe PDF as one that does not permit information processing. HTML is described as static information processing where the data cannot be analysed on the spot (there is a need for additional queries). XBRL is described as dynamic information processing where data can be processed on the 'spot' and/or copied and pasted to software packages such as Excel for analysis (SEC, 2007).

Bertin (1983) argues that different forms of presentation make some aspects of the information displayed more apparent. He noted that one format is not necessarily more effective in solving all tasks where a format that could be used to effectively solve a task may not be so effective in a different task. However, studies that examine the effect of reporting formats on decision quality are inconclusive. Some studies suggest that reporting formats impact decision accuracy and cognitive effort. For example, Using tabular and graphical in their experimental design, Hard and Vanecek (1991) found that the use of such formats impact decision accuracy and cognitive effort, although this impact is not statistically significant. Similarly, Dull et al. (2003) examined non-hyperlinked (PDF) and hyperlinked (HTML) and concluded that reporting formats do not impact decision accuracy and cognitive effort when evaluating large firms.

Studies have suggested that some decision-makers' characteristics such as work experience, familiarity with presentation formats, gender, confidence and personal cognitive style could impact the effectiveness of reporting formats in reaching the decision outcome (Sabherwal and Grover, 1989; Bamber, 1993; Brown and Eining, 1996; Nouri, Douglas, and Clinton, 2006). Kalchelmeier and Messier (1990) found that experience moderates decision accuracy since the more experienced decision-maker brings added skills to their engagement with financial statements produced under different reporting formats.

Decision accuracy and cognitive effort are the most widely used measures to evaluate the effectiveness of a particular reporting format on decision quality (Kleinmuntz and Schkade, 1993). An appropriate reporting format would enhance the structure of the information and assist decision-makers in the processing of information more accurately and with less cognitive effort (Mackay et al. 1992; Hodge et al. 2004). However, there are studies that found that reporting formats do not affect decision quality. These studies have identified other factors that impact decision accuracy and cognitive effort such as confidence (Whitecotton, 1996), degree of processing (Bricker and Nehmer, 1995), task characteristics (Dull et al., 2003), and decision-makers' characteristics (Bizarro and Baldwin 2004).

The null hypotheses testing the link between reporting format, decision accuracy and cognitive effort are developed as follows:

H1 : There are no significant differences in decision accuracy between digital reporting formats.

H2 : There are no significant differences in cognitive effort between digital reporting formats.

4. Research Method
Participants

The participants in this study are drawn from public accounting practitioners in New Zealand. Public accounting practitioners were chosen as they perform a broad range of accounting, auditing, tax, and consulting activities for their clients (Vera-Munoz et al., 2002), and one of their services is likely to be assisting and advising clients in investment decision tasks. Public accounting practitioners are also believed to be one of the principal decision-makers among people who use financial information to make decisions (Goldwater and Fogarty, 1995).

Previous studies that examine digital reporting formats have often used students as proxy for naive decision-makers (e.g., Hodge, 2001; Dull et al., 2003; Hodge et al., 2002; Hodge et al., 2004). Students in general have limited working experience and have different or less developed analytical techniques in comparison with experienced decision-makers (Vera-Munoz et al., 2002). The use of professional subjects, public accounting practitioners, in this study improves the external validity.

Experimental Design

The experiment task involves an investment decision task. The experiment task is adapted from Hodge et al. (2004) with some modification. The main modification includes the information context (investment properties) and the types of financial ratios. The experiment material comprises financial statements of two fictitious firms, Firm A and Firm B. Each set of financial statements includes a statement of financial performance (income statement), a statement of financial position (balance sheet) which includes notes to the accounts, and a statement of cash flows.

The financial statements are presented in three reporting formats: PDF, HTML and XBRL. These reporting formats were chosen because they are commonly used in the reporting of financial reports. The financial statements for both firms were converted to the three digital reporting formats (PDF, HTML, XBRL). Microsoft Excel was used to retrieve and present XBRL financial statements. An SEC Chairman's statement identified Microsoft Excel spreadsheet as one of the softwares that could be used by investors, analysts and others to download and retrieve XBRL tagged financial statements (SEC, 2007). The financial statements in the three reporting formats were made available to participants through a web page.

Pilot Study and Data Collection

A pilot study was conducted before commencing the main experiment to ensure that the main experiment and post experiment questionnaire capture the data relevant to test the hypotheses. Two public practitioners participated in the pilot study. The difficulty in accessing one of the reporting formats faced by one of the participants indicated that some participants may need to be assisted in completing the experimental tasks. Subsequently, similar to Hodge (2001), the participants were given a choice in completing the experiment, in-lab in the presence of the researcher, or out-of-lab.

On the instruction page, participants are requested to attempt the research material in one sitting and use only the information provided. To assess that the two groups, in-lab and out-of-lab, completed the task in a similar manner, such as no prolonged breaks or use of additional material, the average amount of time taken to complete the experiment and the accuracy in calculating ratios by the two groups was compared.

Finally, each participant was randomly allocated to a digital reporting format, PDF, HTML or XBRL. Each participant was requested to complete the research task using the allocated digital reporting format.

Experiment Procedures

All participants were provided with an envelope. The envelope contained a CD. The CD contains a range of information pertinent to the experiment comprising an instruction sheet, a web homepage providing general information about the two firms that are involved in the manufacturing semiconductors, and their respective financial statements. A participant begins the experiment by accessing each firm's homepage and clicking on a link which provides the financial statements and footnotes in the allocated digital reporting format.

After viewing the firm's financial information, the participants were asked to calculate four key ratios. The ratios are return on assets, return on sales, return on fixed assets, and fixed assets turnover. The participants were asked to complete a section on their demographic profile.

Dependent Measures

Hypothesis 1 states there are no significant differences in decision accuracy between the three digital reporting formats. The decision accuracy score for each participant is measured by the proportion of accurately calculated ratios (eight ratios, four ratios for each firm, A and B) (Bricker and Nehmer, 1995; Dunn and Grabski, 2000). The accuracy score (0 to 8) is the dependent measure for testing decision accuracy.

Hypothesis 2 states that there are no significant differences in cognitive effort between the three digital reporting formats. To measure cognitive effort, the continuous-open approach is used (Courneya and McAuley, 1993). The participants were requested to record their starting time of a particular step/stage of the experiment exercise and the time when the step/stage is completed. The total time taken to complete the experiment exercise is the dependent variable for assessing cognitive effort.

5. Results

Table 1 provides the level of work experience of participants (public accounting practitioners). The participants had a wide range of experience which enabled experience to be tested as a moderating influence on decision accuracy and cognitive effort.

<Insert Table I Here>

Twenty-three participants completed the experiment in-lab and 39 participants, out-of-lab. Table 2 provides a comparison between the two groups. Panel A compares the amount of time the subjects took to complete the experiment. The in-lab participants took on average 13.6 minutes while the out-of-lab took 15.8 minutes to complete the experiment. T-test shows no significant differences between the two groups. This indicates that in-lab and out-of-lab participants attempted the

experiment in a similar manner and gives some confidence that the experimental setting did not impact on responses.

<Insert Table 2 Here>

Panel B provides a comparison between the two groups (in-lab and out-of-lab) in relation to the accuracy in extracting and calculating ratios. The results show that on average, the in-lab participants' average accuracy score was about 4.3 while the out-of-lab participants' average score was about 5. A t-test shows no significant difference between the two groups. This indicates that the in-lab and out-of-lab participants attempted the experiment using only the information provided in the experiment instrument. The results of tests comparing in-lab and out-of-lab groups provide some confidence that the different experimental settings did not impact on the research variables, decision accuracy and cognitive effort.

Decision Accuracy

In this section the results from testing hypothesis 1 are presented. Hypothesis 1 states that there are no significant differences in decision-makers' decision accuracy between the three digital reporting formats. Panel A of Table 3 provides the descriptive statistics of the effect of reporting format on decision-makers' decision accuracy. Participants in the XBRL group had the highest mean accuracy score of 5.66, followed by the HTML group with a score of 5.00, and the PDF group with a score of 3.71.

<Insert Table 3 Here>

The results in Panel B, Table 3 indicate that the differences in the impact of digital reporting format on decision accuracy is marginally significant (p=0.06). The results of comparing each reporting format with another format are provided in Panel C. These results indicate that participants using XBRL had higher decision accuracy than participants using PDF (p=0.05). However, no significant difference was found between PDF and HTML (p=0.27), or between HTML and XBRL (p=0.70). Overall, the Tukey HSD test shows a significant difference between the three digital reporting formats on decision accuracy (p=0.05) as shown in Panel D. The results indicate that hypothesis 1 is not supported.

It is possible that the level of decision accuracy is influenced by factors such as participants' work experience (Kachelmeier and Messier, 1990; Abdomohammadi, 1992). ANCOVA is used to assess the effect of digital reporting formats on decision accuracy, after controlling for the participants' experience.

Table 4 shows the ANCOVA results for the impact of digital reporting format on decision accuracy and reporting format after controlling for work experience. The

results indicate that experience is a significant covariate in determining accuracy. The results also suggest that the null hypothesis of no significant differences between the reporting formats on decision accuracy is marginally rejected (p=0.07). This indicates that the effect of reporting format on decision accuracy is lower after controlling for work experience. Overall, the results indicate that hypothesis 1 is not supported.

<Insert Table 4 Here>

Cognitive Effort

Hypothesis 2 states that there are no significant differences in decision-makers' cognitive effort between digital reporting formats. Panel A of Table 5 provides the descriptive statistics of the effect of each reporting format on decision-makers' cognitive effort. The results show that when compared to the participants using PDF or XBRL formats, participants using HTML format spent less cognitive effort in completing the experiment. Specifically, participants in the HTML group took the least time to complete the experiment (14.15 minutes) compared to participants in the XBRL group, who took 14.80 minutes.

<Insert Table 5 Here>

This indicates that participants found it easier to perform the task using HTML compared with the other two digital reporting formats. HTML provides hyperlinks between various parts and allows greater movements between the various sections of the financial reports.

The ANOVA results in Panel B, Table 5 indicate that the impact of digital reporting formats on cognitive effort is not statistically significant (p=0.57). The results of comparing each reporting format with another reporting format are provided in Panel C. These results indicate no significant differences between PDF and HTML (p=0.562) and between HTML and XBRL (p=0.938). The results indicate that hypothesis 2 is supported.

Similar to decision accuracy, it is possible that the level of cognitive effort is influenced by factors such as participants' experience. The results in Table 6 suggest that when controlling for experience, the null hypothesis that reporting formats impact on cognitive effort is not rejected. This indicates that the effect of reporting formats on cognitive effort remains not significant after controlling for work experience. The results also indicate that experience is not significant covariates in determining cognitive effort.

<Insert Table 6 Here>

6. Summary and Conclusion

This study examined the effect of reporting formats on decision quality using an experimental research design involving public accounting practitioners as research subjects. The finding that reporting formats affect decision accuracy is consistent with previous studies (Stock and Watson, 1984; Dickson et al., 1986; Iselin, 1988; Mackay and Villareal, 1987; DeSanctis and Jarvenpaa, 1989; Hard and Vanecek, 1991; Stone and Schkade, 1991; Anderson and Kaplan, 1992; Bricker and Nehmer, 1995; Ramarapu et al., 1997; Frownfelter-Lohrke, 1998; Hodge, 2001; Almer et al., 2003; Bizarro and Baldwin, 2004; Hodge et al., 2004).

The results show that reporting formats impact decision accuracy and support the notion in the psychology literature that different forms of reporting make some aspects of the information displayed more apparent (Bertin, 1983). For example, relying on schematic faces (facial impression such as a smiling dummy indicating a firm with good performance) may better indicate the firm's performance than using ratios (Moriarity, 1979). However, certain reporting formats that can be used to achieve decision accuracy in a specific task may not be effective in a different task. In this case, of the three reporting formats examined, XBRL seems to be the best reporting format to possibly promote decision accuracy in investment decision tasks.

The information systems literature also supports the theory that reporting formats impact decision accuracy. The information systems literature suggests that when reporting format matches the task type, the decision quality improves. Vessey (1991) suggests that if a reporting format does not match the task type, the decision-makers would need to convert the reporting format to a form similar to the task, leading to potential sub-optimal performance. In this study, the task type is investment decisions. Therefore, this study suggests that for investment decision purposes, using PDF or HTML would require the decision-makers to convert the information presented to a more analytical form, and during this process, the decision-makers are likely to make errors, leading to sub-optimal decision performance. In contrast, XBRL allows information processing of the data on the spot, where the data can be extracted and processed automatically by XBRL-aware applications such as Excel for analysis (SEC, 2007).

The results in this study also show that the impact of reporting formats on decision accuracy is lower when decision-makers' work experience is accounted for. Such results are consistent with results of previous studies that suggest decision-makers with more experience in the task are expected to bring added skill to their interactions with the reporting format and therefore, enhanced decision accuracy (Mackay et al., 1992; Bizarro and Baldwin, 2004).

The results in this study show that digital reporting formats do not impact cognitive effort. This is consistent with the findings in So and Smith (2003) and Dull et al. (2003) where reporting formats do not increase the efficiency of decision-making. However, this finding is not consistent with studies that found reporting formats do impact cognitive effort (Benbasat and Dexter, 1986; Jarvenpaa, 1989; Ramarapu et

al., 1997; Tuttle and Kershaw, 1998). It has been suggested that other factors such as task characteristics (Dull et al., 2003), cognitive style (Bizarro and Baldwin, 2004), gender (Nouri and Douglas-Clinton, 2006), and degree of information processed (Bricker and Nehmer, 1995), may impact on cognitive effort.

Most of the studies that used students as subjects show that reporting formats impact on cognitive effort. However, some studies show that less experienced decision-makers have only one supposition and therefore search for information to confirm that supposition (Bouwman, 1982; Biggs et al., 1985; Anderson, 1988). On the other hand, when decision-makers are more experienced, they would have several suppositions in their working memories and search for potential information to contradict and distinguish among these suppositions (Bouwman, 1982; Biggs et al., 1985; Anderson, 1988). Such information processing behaviour would mean a longer time would be taken to complete a task. As a result, with experienced decision-makers, digital reporting formats may not impact on cognitive effort.

Two limitations are identified with this study. First, the number of participants involved in this study is relatively small. However, similar studies have used a small number of participants, such as Tuttle and Kershaw (1998): 39 participants; Hodge (2001): 57 participants; Dull et al. (2003): 60 participants; and Hodge et al. (2002, 2004): 96 participants.

The participants in this study were randomly allocated to digital reporting formats. The performance of participants may be different if they were allowed to choose a digital reporting format.

In summary, the findings in this study suggest that preparers, standard setters and regulatory bodies should recognise that digital reporting formats impact decision-quality and select appropriate formats that lead to improvement in decision-making.

FAIRNESS PERCEPTIONS AND COMPLIANCE BEHAVIOR: NEW ZEALAND EVIDENCE

Natrah Saad[14]

Abstract

The present study fills a gap from the literature through investigating in a rarely examined jurisdiction, namely New Zealand, the role of fairness in tax compliance decisions among taxpayers. The impact of tax knowledge and tax complexity on fairness perceptions are also examined. The study extends the well-established Theory of Planned Behavior (TPB). A questionnaire was administered among taxpayers drawn from the 2008 Preliminary New Zealand Electoral Roll. The findings reveal that overall fairness and vertical fairness positively influence compliance behavior while exchange fairness and administrative fairness have an inverse relationship with compliance behavior. Tax knowledge and tax complexity also affect several fairness dimensions. The variables examined under the TPB are also significant in explaining tax compliance behavior. This study should help tax researchers generally to understand the role of fairness perceptions, tax knowledge, tax complexity and TPB variables in compliance behavior.

1. Introduction

The importance of tax fairness in compliance decisions have been documented in previous studies (for example, Gilligan and Richardson, 2005; Hite and Roberts, 1992; Porcano and Price, 1992; and Song and Yarbrough, 1978). However, those studies, with the exception of Gilligan and Richardson (2005), only deal with either overall fairness or fairness of the tax rate structure. Fairness perceptions can extend far beyond that. Likewise, a substantial number of available studies have tended to focus on the association between fairness perceptions and tax compliance rather than on the factors contributing to fairness perceptions. Thus, this study aims to fill

---

[14] Natrah Saad, the corresponding author, is a PhD student in the Department of Accounting and Information Systems, University of Canterbury, Christchurch, New Zealand. The author wishes to thank her supervisors, Prof. Adrian Sawyer and Andrew Maples for their assistance and comments on earlier versions of this paper. The author can be contacted at nbs24@student.canterbury.ac.nz.

the gap by looking into various dimensions of fairness perceptions and their influences on compliance behavior. Subsequently, the factors contributing to fairness perceptions will be further examined.

I believe this study contributes to the literature in several ways. First, from a theoretical perspective, this study adds to the limited literature available in the Australasian region. To date, there have been two major studies on fairness perceptions undertaken in New Zealand (Tan, 1998; and Hasseldine et al.,1994), but they were both conducted prior to the formal implementation of the current self assessment system. Second, this study extends the well-established Theory of Planned Behavior (TPB) in compliance behavior studies. While the TPB appears to be the dominant model in explaining an individual's behavior, the inclusion of fairness perceptions in tax settings have strengthened the model to a certain extent.

Third, from a practical perspective, the information on taxpayers' fairness perceptions and compliance behavior can assist policy makers, particularly tax authorities in reviewing and modifying current tax systems, where necessary. In addition to this, the findings on the impact of tax knowledge and tax complexity on fairness perceptions and compliance behavior are also useful for policy makers to tailor tax education and simplification programs.

The remainder of this paper is organized as follows. Section 2 provides an overview of the income tax system and compliance environment in New Zealand while Section 3 reviews the relevant literature and develops the research hypotheses. In Section 4, the conceptual model is proposed, while Section 5 describes the methods used. The

results are presented in Section 6, followed by a discussion in Section 7. Finally, the paper ends with concluding remarks in Section 8.

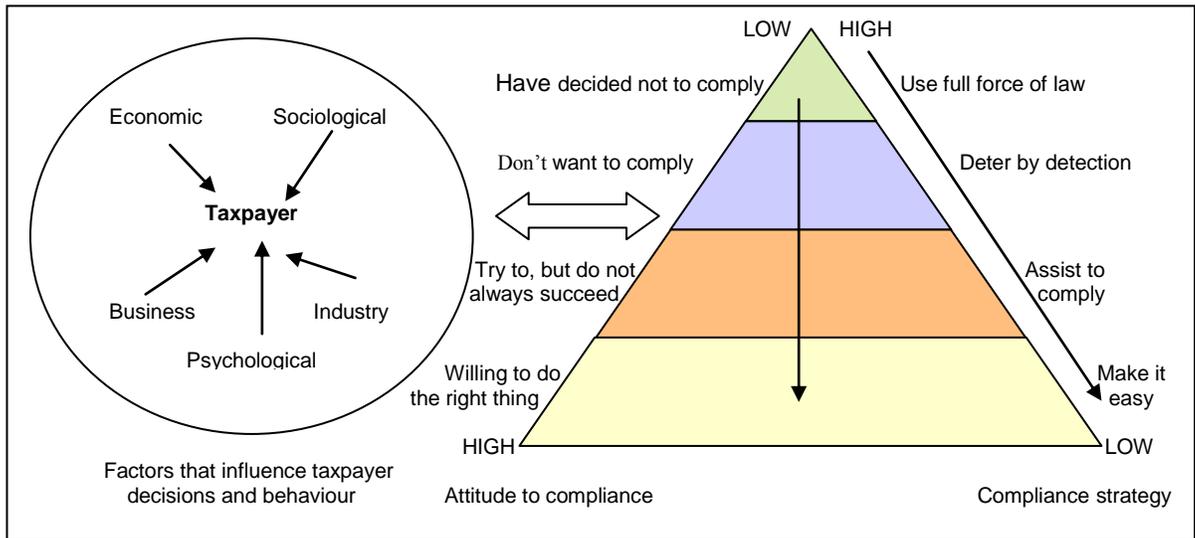
2.   Overview of the Income Tax System and Compliance Levels in New Zealand

The New Zealand income tax legislation was first enacted in 1891 as part of the Land and Income Tax Assessment Act 1891. Since its commencement, numerous reforms have been made to improve the income tax system and deal with an increasingly complex environment (Tax Review, 2001; Tan, 1998). Like many other jurisdictions, New Zealand also relies on a voluntary compliance tax system,[15] for which taxpayers are expected to understand and comply with their tax obligations (Committee of Tax Experts, 1998). Under this voluntary self-assessment system, some taxpayers are prone to non-compliance (both intentional and unintentional). Hence, the Inland Revenue Department (IRD) has taken a proactive stance to maintain high levels of tax compliance, through its Compliance Model (New Zealand Inland Revenue, 2007).

The IRD Compliance Model (based on the Australian Tax Office's Compliance Model) shown in Figure 1, is designed to facilitate compliance amongst the vast majority of taxpayers, and takes into consideration the external factors (economic, sociological, business, industry and psychological) that influence taxpayers' attitudes and behaviors. Once the determining factors are recognized, the most suitable approach is applied to the best way possible to improve compliance.

---

[15] A self assessment system has been formally in place in New Zealand since 1998.

FIGURE 1
The IRD Compliance Model


Source: New Zealand Inland Revenue (2007).

It appears that the IRD's compliance strategy, as represented by the IRD Compliance Model (and the IRD's audit approach), has been particularly fruitful in identifying tax discrepancies. For instance, the most recent data reported in the Annual Report of New Zealand Inland Revenue (2008) indicates a net total discrepancies of NZ$1,449 million as compared to only NZ$996 million in the previous year.

However, the Annual Report suggests that maintaining high levels of voluntary tax compliance is a problem. This is evidenced by the number of taxpayers who were required to file tax returns but did not submit their return forms in the past three years. Eighteen percent of individual taxpayers did not submit their tax return forms both in 2004-05 and 2005-06 years (New Zealand Inland Revenue, 2006), rising to 22 percent in the 2006-07 year (New Zealand Inland Revenue, 2007).

The above statistics were supported by a research undertaken by the IRD in the 2006-07 year (New Zealand Inland Revenue, 2007). This research, carried out on half a million return filing and paying tax events between 2001-2005 years, showed the following preliminary results: (1) 83 percent of the returns complied with the majority completing all relevant filing and tax paying obligations; (2) nine percent of returns had a moderate level of compliance issues; (3) and eight percent demonstrated poor levels of compliance. These findings indicate that at least 17 percent of individual taxpayers in New Zealand have not complied (in some form) with the tax system.[16] It is important to note that this research focuses on taxpayers who have some choice about compliance and excludes taxpayers who are employees and have tax deducted at source through the Pay As You Earn (PAYE) system (New Zealand Inland Revenue, 2007).

In addition, Caragata (1998) reports that the estimated tax gap in New Zealand has increased substantially from NZ$82 million in 1969 to NZ$3.2 billion in 1994. More recent data from the IRD reports an amount of NZ$996 million of tax discrepancies in 2006-07, of which NZ$375 million was due to the tax avoidance and evasion practices (New Zealand Inland Revenue, 2007). The figure shows an increase of 15 percent from the previous year. These statistics could possibly be attributable in part to the tax fairness issue as suggested by Etzioni (1986).[17]

---

[16] The percentage could be higher since the research results clearly stated that most of taxpayers (83 percent) complied with the majority (i.e. not fully complying) of their filing and paying obligations.

[17] However, it must be noted that fairness of the tax system may not have an impact on hard-core evaders' decisions, etc.

The above discussion indicates that the use of the IRD Compliance Model contributes to increasing tax collection through focussed tax audits but not to the same level of promoting voluntary compliance. Thus, the issue of voluntary tax (non)compliance among taxpayers in New Zealand is a very relevant concern.

3. Literature Review and Hypotheses Development

This section provides an overview on the relevant literature on tax fairness perceptions, tax compliance and the variables under investigation, and is followed by hypotheses development.

3.1 Tax fairness perceptions

Previous studies indicate that fairness perceptions can take various forms. First, vertical fairness, which asserts that taxpayers with different economic situations should be taxed at different rates (Erich et al., 2006). This would result in higher income earners paying tax at higher rates than low-income earners. Another component is, horizontal fairness, defined as 'the equal treatment of equally circumstanced individuals' (Michael, 1978). In other words, horizontal fairness recommends that taxpayers of similar economic positions should pay the same amount of tax.

In addition to vertical and horizontal fairness, Bobek's (1997) study on the US tax system is also concerned with procedural fairness and policy fairness. Procedural fairness relates to the process employed to reach distribution outcomes while policy fairness deals with the content of the tax law. Another significant fairness dimension is exchange fairness (Gilligan & Richardson, 2005; Gerbing, 1988), which represents the exchange of contribution and benefit between taxpayers and government. This

dimension of fairness holds that taxpayers will have fair perceptions of the tax system if the benefits received from the government is equitable compared to their tax contributions.

Other dimensions of fairness include a preference for either progressive or proportional taxation (Turman, 1995), personal fairness, tax rate fairness, special provisions and general fairness (Gilligan & Richardson, 2005; Richardson, 2005; Christensen & Weichrich, 1996; Christensen et al., 1994; Gerbing, 1988).

The above review on studies of tax fairness suggests approximately ten dimensions of fairness. However, in this study, five dimensions are identified to be important in assessing the fairness of the income tax system. The dimensions are: overall fairness, exchange fairness, horizontal fairness, vertical fairness and administrative fairness. Overall fairness simply measures individuals' judgments whether the (income) tax system is generally fair or not. While exchange fairness is concerned with a reciprocal exchange between taxpayers and the government, horizontal fairness considers equal tax treatment among taxpayers in similar economic positions. Vertical fairness is assessed based on the ability to pay and preference for tax rate structure, either flat rate or progressive. Administrative fairness, on the other hand, relates to the content of the tax law (policy fairness), procedures employed by the tax authority (procedural fairness) and the fairness of punishments imposed (retributive fairness). Thus, based on the prior literature, it is therefore hypothesised that:

> H_1: *Fairness perceptions on the New Zealand income tax system is multi-dimensional.*

3.2 Tax compliance

In this study, tax compliance is assumed to take place when a taxpayer files all required tax returns at the proper time and that these returns accurately report tax liability in accordance with the tax law applicable at the time the return is filed. This definition is adopted from Roth et al. (1989), as it provides a better definition when compared to the definition used by Jackson and Milliron (1986) (refer to Richardson & Sawyer, 2001).

Numerous studies have been published on the relationship between tax fairness perceptions and tax compliance. Survey data from 1960-1980 by Etzioni (1986) documented that the fairness perception is more likely to affect tax compliance rather than tax rates. Turman (1995) and Roth et al. (1989) confirmed that fairness perceptions influence tax compliance behavior. Similarly, Gilligan and Richardson (2005), Roberts (1994), Hite and Roberts (1992), Porcano and Price (1992), Harris (1989), and Song and Yarbrough (1978) found tax compliance to be significantly associated with perceptions of an improved tax system.

A recent cross-cultural study by Richardson (2005a) on tax fairness perceptions and tax compliance behavior in Australia and Hong Kong documented that tax fairness perceptions about general fairness have a significant impact on tax compliance behavior in both countries. Additionally, in Australia, it was found that tax fairness perceptions about special provisions, tax rate structure and self interest have some significant relationships with tax compliance behavior. Given the foregoing discussion, it is further hypothesised that:

H$_2$: New Zealand taxpayers perceive fairness dimensions$_{1 \text{ to } k}$ positively and significantly influence tax compliance behavior.

3.3   Tax knowledge

Tax knowledge is an essential element in a voluntary compliance tax system (Kasipillai, 2000), particularly in determining an accurate tax liability (Palil, 2005). Without tax knowledge, there is a tendency for taxpayers not to comply with the tax law either intentionally or unintentionally. This is postulated by McKerchar (1995) who studied small business taxpayers. She suggests that small business taxpayers are not even aware of their tax knowledge shortfall and this may lead to unintentional non-compliance behavior.

The influence of tax knowledge on fairness perceptions was documented by Schisler (1995), who carried out a study comparing tax preparers and taxpayers. Schisler found that taxpayers have significantly lower fairness perceptions compared to tax preparers. The result might be due to the absence of tax knowledge among taxpayers compared to tax preparers. Fallan (1999) later confirmed Schisler's (1995) findings that tax knowledge significantly changed attitudes towards the fairness of the tax system. In that experimental study, the author measured tax knowledge through an additive index of 12 questions concerning tax allowances and tax liabilities.

Unlike Fallan (1999), who simply focused on technical knowledge of tax, an earlier study by Harris (1989) separated tax knowledge into fiscal awareness and technical knowledge, in order to observe the impact of each type of knowledge on fairness perceptions. The findings reveal that types of tax knowledge impact fairness

perceptions and consequently compliance behavior. This study is supported by White et al. (1990), who suggested that a formal class in taxation would enhance the knowledge about the law and appreciation of fiscal policy goals, thus increasing perceived fairness.

Despite the evidence that fairness is a multi-dimensional construct, these prior studies tend to focus on the effect of tax knowledge on the overall fairness of the tax system rather than on each dimension of fairness. To critically assess the role of tax knowledge on fairness perceptions of the tax system, I believe it is essential not only to distinguish the types of knowledge, but also the dimensions of fairness that the type of knowledge has affected. Having said that, this study examines the impact of tax knowledge on five dimensions of fairness as discussed earlier. Thus, it is hypothesised that:

> H_3: *Tax knowledge positively influences the dimensions of fairness perception$_{1\ to\ k}$ of New Zealand taxpayers.*

3.4   Tax complexity

Tax complexity arises due to the increased sophisticatication in the tax law (Richardson & Sawyer, 2001). In New Zealand, Tan and Tower (1992) claimed that the efforts made by the tax authority at that stage to simplify the tax law had failed. In their study, the authors applied the Flesch Reading Ease Index to measure the readability level of New Zealand tax legislation, Tax Information Bulletins (TIBs) and Tax Return Guides. The Flesch Reading Ease Index measures the difficulty ranging from zero (most difficult) to 100 (least difficult). The authors' findings indicated that there was no progress with simplification at that time, except for the Tax Return

Guides. Tan and Tower (1992) recommend that shorter sentences and active style of writing will help improve the readability of tax legislation and consequently reduce the complexity of the tax law.

A more recent study by Pau et al. (2007) provides contrary evidence on tax simplification in New Zealand. The researchers test the effectiveness of the (then) newly written Income Tax Act 2004[18] (partially completed), TIBs and binding rulings using readability measures, namely the Flesch Reading Ease Index, Flesch-Kincaid Grade Level Index, average sentence length and percentage of passive sentences. Pau et al. (2007) found significant improvements in respect of tax simplicity through these measures. Sawyer (2007) agrees with the authors that there have been some improvements in tax simplification but continual change to the legislation has to a certain extent delayed the rewrite programme (and also delayed the benefits). As a consequence, the rewrite programme has only recently been completed, after more than a decade.[19]

Some researchers agree that a certain degree of complexity in the income tax system is necessary to ensure the system is fair. This is particularly applicable to the perceptions of the tax authority and tax professionals, suggests White (1990). Applying four scenarios of tax complexity, she asserts that both the tax authority and tax professionals (tax lawyers and tax accountants) prefer complexity in the tax law but at different levels. The tax authority prefers tax complexity that will increase their

---

[18] This legislation contains further changes to Parts A and B, the rewritten sections of Parts C, D and E, with re-enactment of the remaining parts of the Income Tax Act (Pau et al., 2007).

[19] The rewrite programme started in 1993 and the final stage was passed by the New Zealand Parliament on October 25, 2007 (Sawyer, 2007).

probability to win the cases in disputes, while tax lawyers on the other hand are in favor of tax complexity that gives rise to a higher probability that the taxpayers will win the case. Similarly, tax accountants' preferences are also towards a high level of tax complexity as it will increase the demand for their tax services. In his critique and extension of White's study, Sawyer (1996) suggests that the tax authority prefers a lower level of tax complexity than indicated in White (1990), and the tax authority may benefit most when the level of complexity is close to zero in some circumstances.

Notwithstanding preferences by the tax authority and tax professionals, tax complexity actually causes negative perceptions of fairness among taxpayers (Cialdini, 1989; Carroll, 1987). Milliron (1985) claims in her study of jurors that the participants viewed complexity and fairness as distinct but incompatible features of the income tax system. Erich et al. (2006) share a similar view on the inverse relationship between complexity and fairness perceptions. In their study on Australian taxpayers and tax officers, Erich et al. (2006) claim that complexity in tax law results in a negative perception of the tax system and consequently encourages an unwillingness to comply. Based on the foregoing discussion, it is therefore hypothesised that:

> H_4: *Tax complexity negatively influences the dimensions of fairness perception$_{1\ to\ k}$ of New Zealand taxpayers.*

3.5 Theory of Planned Behavior

The Theory of Planned Behavior (TPB) is the extended version of the Theory of Reasoned Action (TRA), and is a dominant theoretical framework used in explaining

human behavior (Ajzen, 1991). The TPB model depicts that behavioral intention is the immediate determinant of the actual behavior. Behavioral intention is, in turn, determined by attitude towards behavior, subjective norm and perceived behavioral control. Some examples that have successfully applied TPB in predicting behaviors include speeding (Paris & Broucke, 2008), adolescent smoking (Guo et al., 2007) and cardiopulmonary resuscitation (CPR) involvement (Dwyer & Williams, 2002). In a taxation context, Bobek (1997) applied the TPB model with the inclusion of the moral obligation variable.

3.5.1   Attitude towards compliance

Ajzen (1991) stipulates that attitude towards compliance reflects feelings of favor and disfavor towards compliance behavior. The contention has been shown by Davis et al. (1989) in information technology studies. In a taxation context, Bobek (1997) found that attitude explains compliance behavior when the belief-based attitude measure is used. A recent study by Loo et al. (2007) also emphasizes that attitude towards the tax system positively influences the compliance behavior. Thus, it is anticipated in this study, that a positive attitude towards the tax system would encourage taxpayers to comply and vice versa.

3.5.2   Subjective norm

Subjective norm reflects motivation to conform with significant referents either to comply or not comply with tax obligations. A review of factors affecting compliance from 1986 to 1997 reveals compliance with peers as significantly related to compliance behavior (Richardson & Sawyer, 2001). This view is supported by Bobek (1997) who found that subjective norm significantly affects compliance

behavior in a business deduction scenario. A comparative study in Australia, Singapore and the US by Bobek et al. (2007) also found subjective norm as an influential factor in explaining tax compliance behavior. Based on the literature, I expect subjective norm would positively influence taxpayers in their compliance decisions.

3.5.3 Perceived behavioral control

Perceived behavioral control reflects an individual's perception on the ease or difficulty in performing a particular behavior. Azjen (1985) stipulates that a behavior that is easy to perform is high in perceived behavioral control, while one that is difficult to perform is low in perceived behavioral control. Furthermore, the author suggests that an individual with high perceived behavioral control will be more likely to perform the behavior in context than an individual with lower perceived behavioral control.

In tax compliance behavior research, when a taxpayer believes that he or she can successfully complete and file the tax return forms with Inland Revenue without any mistakes, the person seems to have a high perceived behavioral control and is more likely to comply with their tax obligations. Likewise, if a taxpayer believes that he or she can avoid paying tax without being caught by a tax audit, the person also seems to have a high perceived behavioral control over non-complying, and thus, is more likely to avoid paying tax.

In this study, I am interested in respondents' perceived behavioral control over non-complying with tax obligations. In particular, I anticipate that the higher the perceived

behavioral control, the more likely that the taxpayers would avoid compliance. Based on the foregoing discussion on the TPB, it is therefore hypothesised that:

H_{5a}: *Attitude towards compliance and subjective norm positively influence tax compliance behavior of New Zealand taxpayers; and*

H_{5b}: *Perceived behavioral control negatively influences tax compliance behavior of New Zealand taxpayers.*

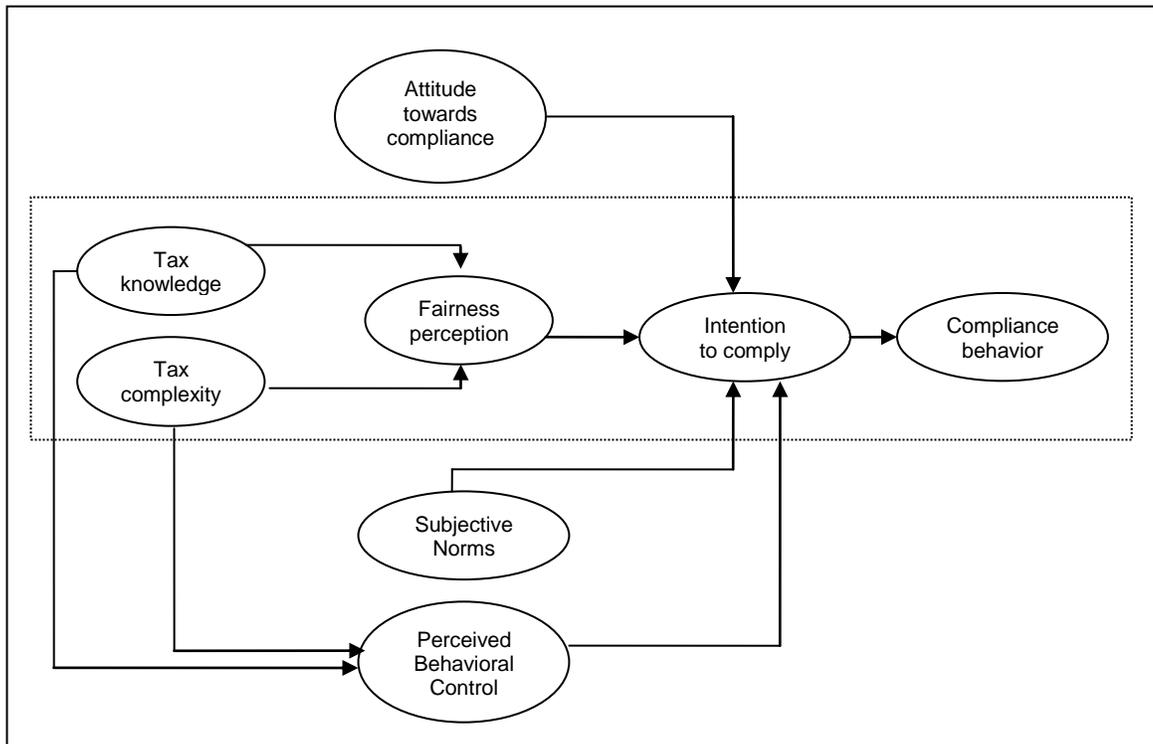
As indicated earlier, perceived behavioral control deals with how taxpayers perceive relative easiness and difficulty in non-complying with tax obligations. As taxation is inherently a complicated matter, it is more likely that taxpayer's control over non-complying with tax obligations is influenced by resources and obstacles. Based on this argument, it is appropriate to investigate the impact of tax knowledge (resources) and tax complexity (obstacles) on perceived behavioral control. Therefore, it is hypothesised that:

H_{6a}: *Tax knowledge positively influences perceived behavioral control of New Zealand taxpayers.*

H_{6b}: *Tax complexity negatively influences perceived behavioral control of New Zealand taxpayers.*

4.   Proposed Model

I now propose a model, as set out in Figure 2, that incorporates the factors that may influence fairness perceptions and compliance behaviour as discussed earlier. A description of each construct employed in the model is also presented.

FIGURE 2
Factors Affecting Fairness Perceptions and Compliance Behavior


5.   Methodology

This section outlines the data collection and sampling characteristics, measurement

techniques, demographic information and data analysis.

5.1   Data collection and Sampling

Data were collected through a postal survey. A total of 2,267 questionnaires were

mailed to taxpayers. The questionnaire included a total of 85 items, including items

not included in the analysis within this study. Since there is no identifying coding on

the questionnaire, a reminder was mailed to all of those in the first mail out to

increase the response rate. A total of 229 usable responses were received for a

response rate of 10 percent. While the response rate is low (refer Slemrod & Venkatesh, 2002) the absolute number of responses is sufficient for further analysis. The sample comprise of New Zealanders listed on the 2008 Preliminary Electoral Roll. The Electoral Roll is a list of all registered New Zealand voters over the age of 18 years and will include most New Zealand individual taxpayers. A major limitation is that it will also include taxpayers who do not have to file tax returns but receive a Personal Tax Summary (PTS). Nonetheless, the use of the Electoral Roll in tax studies has been previously undertaken in New Zealand by Hasseldine et al. (1994).

5.2   Measurement techniques

Twelve items were used to measure the five dimensions of fairness. Out of these, four items were adapted from the previous study (Gilligan & Richardson, 2005) while the remaining items were self-developed with reference to the concept of fairness in Equity Theory and the New Zealand income tax system. The items were scaled such that a higher number reflects a fairer perception.

For compliance behavior, a hypothetical tax scenario relating to overstating expenses was developed. Following the scenario, 14 statements relating to the TPB variables (intention, attitude, subjective norm and perceived behavioral control) were generated and the respondents were requested to express their opinions on the statements. Intention, attitude and subjective norm were scaled such that a higher number corresponds to more compliance with tax obligations. In this study, compliance behavior was measured through its proxy, intention to comply. Perceived behavioral control, on the other hand, measures control over non-

complying with tax obligations and was scaled such that a higher number reflects higher control over non-compliance.

Three items to measure tax knowledge were developed based on various definitions available in previous studies. These items represent general knowledge, legal knowledge and technical knowledge. To measure tax complexity, six items were developed measuring both content and compliance complexity. Tax knowledge was coded such that a higher number reflects higher tax knowledge. Tax complexity, on the other hand, was scaled such that a higher number corresponds to a lower level of tax complexity.

All items were developed based on the 7-point Likert Scale, from strongly disagree (1) to strongly agree (7). In addition, respondents were also asked to provide demographic background information, including age, gender, ethnicity, education level, annual income, source of income and filing experience.

5.3   Demographic information

The relevant demographic information of the sample and the descriptive analysis of the responses are set out in Table 1, Table 2 and Table 3, respectively.

From Table 1, it shows that 60.7 percent of the respondents are in the range of 30s to late 50s age group. While male and female respondents are almost equally represented, 50 percent of them are at least, holders of a diploma or degree. With regard to filing experience, the majority (73 percent) have filed their tax returns for more than five times.

TABLE 1
Summary of Demographic Data (n = 229)

Variable	Frequency	Percent	Variable	Frequency	Percent
Age (years)			**Annual income**		
Under 20	3	1.3	Less than $20,000	44	19.2
20-29	18	7.9	$20,000-$30,000	25	10.9

Masters or PhD	26	11.4			

Table 2 describes respondents' perceptions on the fairness of the income tax system, tax knowledge and tax complexity. Referring to the mean, it appears that taxpayers have positive perceptions on the tax system in relation to overall fairness and horizontal fairness, but negative perceptions on exchange fairness. Taxpayers have neutral perceptions on vertical fairness and administrative fairness. The respondents consider themselves as knowledgeable about tax, yet view the tax system as complex.

5.4 Analysis

The hypothesised model was analysed using a partial least squares (PLS) approach.

This approach is suitable for models with latent variables which cannot be measured

directly. In addition, PLS is considered appropriate due to its ability to model latent

constructs under conditions of nonnormality and small to medium sample sizes

(Jones et al., 2002; Chin, 1998; Chin & Gopal, 1995). The model was tested by

performing a bootstrap procedure in the PLS.[20]

Prior to analyzing the structural model, several statistical analyses were carried out.

To ensure that the respondents are representative of the respective populations, a

non-response bias test was performed by comparing early responses to responses

generated after follow-ups. There was no significant differences found between the

---

[20] The software used for the analysis was PLSGraph Version 3.0 developed by Professor Wynne Chin of the University of Houston.

two groups enabling the researchers to conclude that there was no evidence of any nonresponse bias.

To examine the reliability of the constructs, a measure of internal consistency, known as composite reliability, was computed. The results (as exhibited in Table 4) indicate that the composite reliability for all constructs were above the threshold level of 0.6 (Bagozzi & Yi, 1988).

Convergent validity was examined by looking at two indices: (1) the individual item loadings on the constructs; and (2) the average variance extracted (AVE). From 21 items measuring fairness perceptions, tax knowledge and tax complexity, the individual item loadings on the constructs were all highly significant at 0.7 and above (Dibbern & Chin, 2005) with a significant t-value of 0.05 level (Gefen & Straub, 2005), with the exception of six items. In relation to tax compliance behavior constructs, all items except for one item measuring perceived behavioral control (with item loading of 0.639), were highly significant with individual loadings of 0.7 and above. The item with a loading below 0.7, however, may still be acceptable since there are other additional indicators for that construct (Chin, 1998). In terms of AVE, all constructs in that Scenario had values above the threshold of 0.5 (Bagozzi & Yi, 1988). Tax complexity had a marginally low AVE of 0.46 (refer Table 4).

To assess discriminant validity, the average variance extracted shoud be compared against the correlations among constructs. As a rule of thumb, the AVE of each construct should be larger than the correlation of the specific construct with any of the other constructs in the model (Gefen et al., 2000) to assure the discriminant validity. This condition was met in this study as exhibited in Table 5, suggesting the existence of discriminant validity.

Table 5

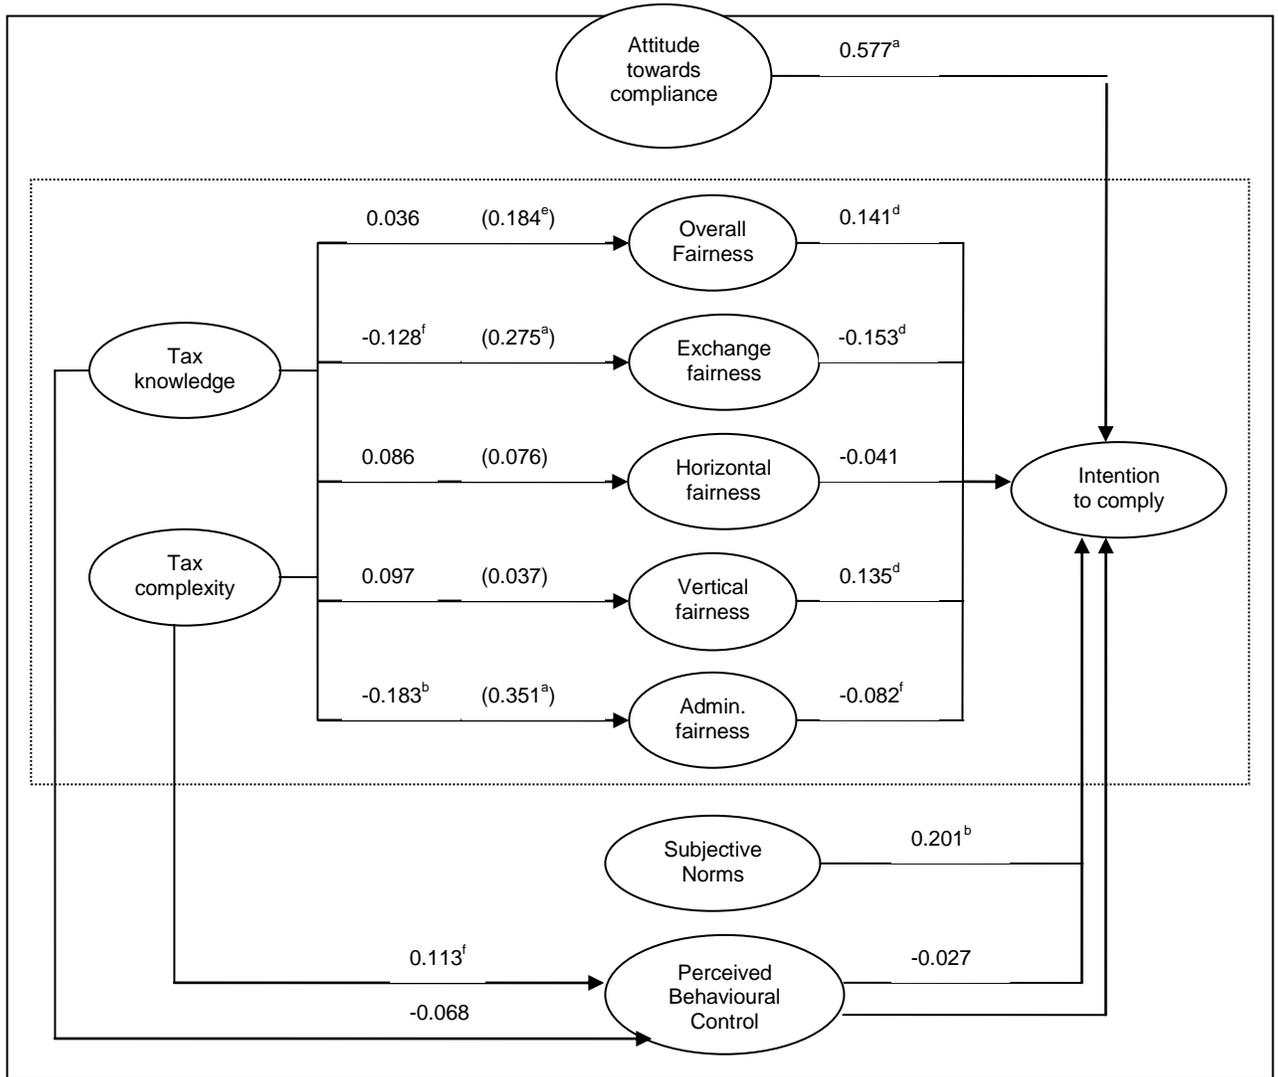
Figures in diagonal represent the average variance extracted.

6. Results

Figure 3 presents the results. The R^2 for the intention to comply at 0.538 is a considerable improvement over the reported R^2 in Bobek (1997), who studied the determinants of non-compliance behavior. The path coefficients on variables under study are also provided. In relation to the direct effects of fairness perceptions on compliance behavior, it is found that horizontal fairness was not a significant factor. All other dimensions of fairness were significant at the 0.025 level, except for administrative fairness, which was marginally significant at the 0.10 level. Both overall fairness and vertical fairness positively influenced compliance behavior. Surprisingly, however, path coefficients for exchange fairness and administrative fairness indicate the opposite direction to that expected.

The TPB variables were highly significant at the 0.001 (attitude) and 0.005 (subjective norm) levels. As expected, attitude and subjective norm positively influenced compliance behavior. Perceived behavioral control had a negative effect on compliance behavior but not significant.

FIGURE 3
Path Coefficients


Notes:
Figures in parentheses are path coefficient for tax complexity on fairness perceptions.
$R^2 = 0.538$
[a] $p<0.001$
[b] $p<0.005$
[c] $p<0.010$
[d] $p<0.025$
[e] $p<0.050$
[f] $p<0.100$

159

The model also describes the path coefficients for tax knowledge and tax complexity on fairness perceptions. The results show that tax knowledge had negative direct effects on exchange fairness and administrative fairness at the 0.10 and 0.005 levels, respectively. Other variables were not significant. For tax complexity, the results reveal that horizontal fairness and vertical fairness were not significant. The other paths had a significant positive influence on fairness perceptions at the 0.001 level, except for overall fairness with significant level of 0.05. Tax complexity (but not tax knowledge) had a significant positive influence on perceived behavioral control at the 0.10 level.

7.   Discussion

The purpose of this study was to examine the fairness perceptions of New Zealand taxpayers on the income tax system and how their perceptions influence the compliance behavior. In so doing, I used a well-established model of the TPB. The TPB model provides a theoretical framework of behavioral determinants consisting of attitude, subjective norm and perceived behavioral control. For the purpose of this study, fairness perceptions were included to extend the existing TPB model, particularly in the tax compliance environment. The TPB model was tested using the data obtained from actual taxpayers. Overall, the results suggest that the TPB model fits the data well.

This study reveals that taxpayers view fairness of the income tax system from various perspectives, namely overall fairness, exchange fairness, horizontal fairness, vertical fairness and administrative fairness. This is consistent with previous studies which contend that fairness perceptions are multidimensional (Gilligan & Richardson,

2005; and Gerbing, 1988). Thus, the findings provide support for Hypothesis 1 that fairness perceptions are multidimensional.

Hypothesis 2 predicts that fairness perceptions will positively influence compliance behavior. Specifically, the hypothesis suggests that the fairer taxpayers perceive the tax system, the more likely they will comply with their tax obligations. However, this is only correct for overall fairness and vertical fairness. The findings support the concept in Equity Theory and are consistent with previous studies (for example, Gilligan & Richardson, 2005; Turman, 1995; Roberts, 1994; and Porcano & Price, 1992). Other fairness dimensions, however, are not significant. Surprisingly, exchange fairness is found to have a negative effect on compliance behavior. A possible explanation for this is that the mean for the exchange fairness variable is below 4.0, suggesting that most respondents perceived the tax system as unfair. Similarly, the inverse relationship between administrative fairness and compliance behavior may be attributable to the fact that the respondents are neutral about administrative fairness as indicated by its mean of 4.0.

Tax knowledge proves to have an influence on exchange fairness and administrative fairness. The findings, however, do not provide support to Hypothesis 3 which predicted that tax knowledge will positively influence fairness perceptions. Also, the findings are not consistent with previous studies (Fallan, 1999; White et al., 1990; and Harris, 1989), which claimed that tax knowledge will increase fairness perceptions. The negative relationship, on the other hand, suggests that taxpayers with a higher of level of tax knowledge found these fairness dimensions to be unfair. This result may have arisen because the majority of respondents have a good

knowledge of tax (based on the fact that 73 percent have filed their tax returns more than five times and 50 percent are at least diploma or degree holders), and they perhaps felt that they are not receiving sufficient benefits in return for their tax paid. In relation to the inverse relationship between tax knowledge and administrative fairness, this is possibly due to the fact that the respondents are unsure about administrative fairness itself.

With regard to tax complexity, the findings indicate that overall fairness, exchange fairness and administrative fairness are highly influenced by tax complexity. The findings are consistent with Hypothesis 4, which suggests that tax complexity has an inverse relationship with fairness perceptions. Specifically this study confirms that a lower level of tax complexity has positively influenced fairness perceptions as reported in previous studies (Erich et al., 2006; Cialdini, 1989; Carroll, 1987; and Milliron, 1985).

The use of the TPB model in tax compliance behavior offers a good explanation of taxpayers' behavior. Attitude and subjective norm proved to be significant factors but not the perceived behavioral control. While attitude and subjective norm have positive coefficients, the perceived behavioral control has a negative coefficient (but not significant). In other words, the results suggest that the higher the attitude towards compliance, the more likely a taxpayer will comply with his or her tax obligations. Similarly, the higher a taxpayer's motivation to comply with his or her referent group, the higher would be their compliance. The findings provide support to Hypothesis 5a. This suggests that the TPB is not limited to predicting unethical behaviors in information systems (Dwyer & Williams, 2002) and other human

behaviors (Paris & Broucke, 2008; Guo et al., 2007; and Chang, 1998), but is also useful in explaining tax compliance behavior.

The final hypothesis predicts that tax knowledge and (tax complexity) will positively and (negatively) influence perceived behavioral control. Specifically, I anticipate a higher level of tax knowledge will result in a higher perceived behavioral control while a higher level of tax complexity will result in a lower perceived behavioral control. The findings on these variables, however, show insignificant results with an exception to the influence of tax complexity on perceived behavioral control. Specifically, the results indicate that taxpayers' perceived behavioral control are higher when the level of tax complexity is low and vice versa. This is consistent with the hypothesis that tax complexity is inversely related with perceived behavioral control.

8.   Conclusion, Limitations and Future Research

The study has identified several dimensions of fairness perceptions as being important determinants of compliance behavior. Furthermore, it provides evidence that attitude and subjective norm as highlighted in the TPB, are also significantly influential. This empirical evidence should add to the literature on compliance behavior. In New Zealand particularly, the findings would provide an important update on the existing evidence documented by Hasseldine et al. (1994) and Tan (1998). Furthermore, the findings should be beneficial to policy makers and the tax authority as they highlight the fairness dimensions and relevant factors that need attention. For instance, the tax authority and policy makers should pay more

attention to providing the necessary facilities or infrastructure (for example, education, health, social welfare) to taxpayers, in return for their tax paid. This implies exchange fairness, of which the taxpayers in this study were more concerned with.

This study should also help tax researchers generally to understand the role of tax knowledge and tax complexity in fairness perceptions. For policy makers, the empirical evidence offers guidance in developing tax education and simplification programmes. Last, but by no means least, this study provides clear evidence that the TPB model has significant potential to contribute to the tax compliance literature. The extension to the TPB model in a tax environment seems to be a fruitful area for future research.

This study, however, is not without limitations. First, the survey response rate of 10 percent is considered low by comparison to previous research. However, with an absolute number of 229 responses, this is sufficient to provide the basis for thorough analysis. Second, the convergent validity analysis on the constructs indicate a lower item loadings than the recommended threshold of 0.7 for some of the items. Notwithstanding the low loadings, the items are still acceptable for further analysis (Chin, 1998). Future research should continue to extend the theoretical model of the TPB in the tax literature as it offers a good explanation of compliance behavior. Possibly researchers could decompose the TPB variables to gain a better insight into the determining factors. In addition, a survey on fairness perceptions among tax professionals would also be an interesting area for research.

1.3 Earnings Management

DOES INVESTOR PROTECTION AFFECT THE CHOICE OF EARNINGS MANAGEMENT METHODS THROUGH REAL ACTIVITY MANIPULATION AND ACCRUAL MANIPULATION? ASIAN COMPARISON

Ratna Candra Sari, Gadjah Mada University
Sony Warsono, Gadjah Mada University
Sri Suryaningsum, Universitas Pembangunan Nasional Veteran Yogyakarta

Abstract

This paper examines systematic differences in earnings management through real activity manipulation and accrual manipulation across 7 Asia countries. We propose arguments that in economies with high investor protection, manager prefer to manage earnings through real activity manipulation rather than through accrual manipulation because accrual manipulation is more likely to draw auditors or regulators scrutiny than real decisions about pricing and production. Our findings are consistent with our prediction. Despite being in economies with high investor protection, managers still have bigger discretion in managing earnings through real activities rather than accrual manipulation.

Keyword: earnings management, real activity manipulation, investor protection

INTRODUCTION

The protection of investor rights, particularly outside investors, is important in creating economic incentives for the development of financial markets (Hart, 1995). More developed financial markets create greater external financing opportunities for firms because legal systems protect investors by conferring on them rights to discipline insiders (e.g., to replace managers), as well as by enforcing contracts designed to limit insiders' private control benefits (e.g., La Porta et al., 1998; Nenova,

2000; Claessens et al., 2002; Dyck and Zingales, 2002).2 Thus, legal systems protecting outside investors reduce insiders' need to conceal their activities.

This paper focuses on investor protection as a significant determinant of earnings management activity. Leuz (2003) argues that strong and well-enforced outsider rights limit insiders' acquisition of private control benefits, and consequently, mitigate insiders' incentives to manage accounting earnings because they have little to conceal from outsiders. This insight suggests that the pervasiveness of earnings management is increasing in private control benefits and decreasing in outside investor protection.

Prior research documents greater financial transparency in countries with stronger investor protection regimes (Bhattacharya et al. 2003; Bushman et al. 2004), and there is evidence that earnings are less managed and in these countries (e.g., Ball et al. 2000; Hung 2000; Leuz et al. 2003). Leuz finds that earnings management is more pervasive in countries where the legal protection of outside investors is weak, because in these countries insiders enjoy greater private control benefits and hence have stronger incentives to manipulate firm performance.

Roychowdhury (2006) finds evidence that managers in US firms manipulate earnings through real activity. Roychowdhury finds evidence suggesting price discounts to temporarily increase sales, overproduction to report lower cost of goods sold, and reduction of discretionary expenditures are used to improve reported margins. This is contrary to Leuz's finding that in countries with strong legal protection, managers are less aggressive to manage earnings. We argue that in

strong legal enforcement economies, managers prefer to manage earnings through real activity manipulation rather than through accrual manipulation.

The manipulation of real activity potentially reduces firm value. Real activities manipulation can reduce firm value because actions taken in the current period to increase earnings can have a negative effect on cash flows in future periods. For example, aggressive price discounts to increase sales volumes and meet some short-term earnings target can lead customers to expect such discounts in future periods as well. This can imply lower margins on future sales. Overproduction generates excess inventories that have to be sold in subsequent periods and imposes greater inventory holding costs on the company. There is evidence that managers manipulate real activity in strong investor protection country (Roychowdhury 2006). So the purpose of this study is to examine whether legal systems affect the choice of earnings management methods.

According to surveys conducted by Bruns and Merchant (1990) and Graham et al. (2005), financial executives indicate a greater willingness to manipulate earnings through real activities rather than accruals. There are at least two possible reasons for this. Firstly, accrual manipulation is more likely to draw auditor or regulator scrutiny than real decisions about pricing and production. Secondly, relying on accrual manipulation alone entails a risk. The realized year-end shortfall between un-manipulated earnings and the desired threshold can exceed the amount by which it is possible to manipulate accruals. If that happens, and reported income falls below the threshold, real activities cannot be manipulated at year-end. So, we argued that in countries with high investor protection, managers don't have discretionary to

manage earnings through accrual manipulation because accrual manipulation is easily to detect. Managers will prefer to manage earnings through real activities.

This study focuses on Asia countries to make contributing to the future of our society and Asia by expanding its range of the responsibilities through legal enforcement and investor protection in order to enhance economic development, mutual understanding and cooperation in Asia. The East Asian countries of Hong Kong, Malaysia, Singapore, Indonesia, Japan, Korea and India provide a useful setting for testing the importance of investor protection. These countries have accounting standards that are generally viewed as high-quality, but (with the possible exception of Hong Kong). They have institutional structures that give preparers incentives to issue low-quality financial reports. Reporting quality of earnings ultimately is determined by the underlying economic and political factors influencing managers' and auditors' incentives, and not by accounting standards per se. Shareholder litigation is an important mechanism to enforce high quality financial reporting—particularly timely loss recognition—in common-law countries. The Asian countries experience comparatively little litigation. Saudagaran and Diga (2000) report that there have been no cases of judicial actions against auditors in Malaysia and Thailand. While there have been lawsuits against auditors in Singapore and Hong Kong, they are less frequent than in common-law countries (Choi et al., 1999).

While prior research has provided evidence on managers' incentives for earnings management and earnings management more aggressive in countries with low legal enforcement but there is relatively little evidence on what manager's methods to manage earnings in different legal environment. In addition, prior

research used accrual manipulation to measure earnings management but actually managers have flexibility to manage earnings with accrual manipulation, real activities manipulation or classification shifting. This paper attempts to provide evidence that investor protection determines manager's choices between real activities manipulation versus accrual manipulation when they have the flexibility to engage both. To measure earnings management through real activity manipulation we use Roychowdhury's model.

Firstly, this study is useful to identify factors that affect method choice by manager to manage earnings. Secondly, this study gives our understanding to evaluate effectiveness of legal enforcement in protect outsider (minority) investor when manager have flexibility to choose earnings management method.

HYPOTHESIS

Legal systems protect investors by conferring on them rights to discipline insiders (e.g., to replace managers), as well as by enforcing contracts designed to limit insiders' private control benefits (e.g., La Porta et al., 1998; Nenova, 2000; Claessens et al., 2002; Dyck and Zingales, 2002).2 As a result, legal systems that effectively protect outside investors reduce insiders' need to conceal their activities. Earnings management can be defined as non-neutral financial reporting in which managers intervene intentionally in the financial reporting process to produce some private gain (Schipper 1989). Managers can intervene by modifying how they interpret financial accounting standards and accounting data, or by timing or structuring transactions (Healy and Wahlen 1999).

Prior accounting research has documented three main methods of earnings management. The most commonly studied method is accrual management (e.g., Healy 1985; Jones 1991; McNichols and Wilson 1988; Rangan 1998; Teoh et al. 1998; Phillips et al. 2003). A second type of earnings management can occur through the manipulation of real activities, such as providing price discounts to increase sales and cutting discretionary expenditures, to manage earnings (e.g., Baber et al. 1991; Dechow and Sloan 1991; Bushee 1998). Third type of earnings management tools is the misclassification of items within the income statement.

We focus on accrual manipulation and real activities because in study comparison across countries, earnings management through classification shifting can be detected if these countries use the same standard. Real activities manipulation as departures from normal operational practices is motivated by managers' desire to mislead at least some stakeholders into believing certain financial reporting goals have been met in the normal course of operations. These departures do not necessarily contribute to firm value but the departures enable managers to meet reporting goals. Certain real activities manipulation methods, such as price discounts and reduction of discretionary expenditures, are possibly optimal actions in certain economic circumstances. However, if managers engage in these activities more extensively with the objective of meeting/beating an earnings target, they are engaging in real activities manipulation (Roychowdhury, 2006).

Bruns and Merchant (1990) and Graham et al. (2005), indicate that financial executives have greater willingness to manipulate earnings through real activities rather than accruals. There are at least two possible reasons for this. Firstly, accrual

manipulation is more likely to draw auditor or regulator scrutiny than real decisions about pricing and production (Dechow, Sloan dan Sweeney 1996). Secondly, relying on accrual manipulation alone entails a risk. The realized year-end shortfall between un-manipulated earnings and the desired threshold can exceed the amount by which it is possible to manipulate accruals. If that happens, and reported income falls below the threshold, real activities cannot be manipulated at year-end.

A number of studies discuss the possibility that managerial intervention in the reporting of financial statement process can occur not only via accounting estimates and methods, but also through operational decisions. Manipulation by management through real activities is less likely to draw auditor or regulator scrutiny. In contrast accrual manipulation is more easily to detect. We therefore propose that earnings management through accrual manipulation is less pervasive in countries where the legal protection of outside investors is strong, because in these countries legal system protect investor by conferring on them right to discipline insider.

H1: There is negative relationship between investor protection and abnormal accruals. Countries with high investor protection exhibit lower abnormal accruals than in countries with weak investor protection.

There is evidence that manager in US firms manipulate earnings through real activity (Roychowdhury, 2006). US firms are characterized by large stock markets, low ownership concentration, extensive outsider rights, high disclosure, and strong legal enforcement. Leuz (2003) finds that in countries with strong legal protection,

176

managers are less aggressive to manage earnings through accrual manipulation. So we argue that in strong legal enforcement economies, managers prefer to manage earnings through real activity manipulation rather than accrual manipulation. Accrual manipulation is more easily to detect, in other hand, real activities manipulation can be subjective, auditors might be limited in their ability to verify the appropriate classification. In countries with low legal enforcement, managers have great discretionary to manage earnings with both accrual manipulation and real activity manipulation. In hypothesis 2 we argue that when legal enforcement strong, managers prefer to manage earnings through real activity manipulation, such as: sales manipulation, reduce discretionary expenses reduction and production increases rather than accrual manipulation.

H2b: There is positive relationship between investor protection and real activity manipulation.

RESEARCH METHOD

MEASUREMENT OF EARNINGS MANAGEMENT THROUGH REAL ACTIVITY MANIPULATION

Real activities manipulation is departures from normal operational practices, motivated by managers' desire to mislead at least some stakeholders into believing certain financial reporting goals have been met in the normal course of operations (Roychowdhury, 2006).

To detect real activities manipulation we investigate patterns in CFO and production costs following Roychowdhury (2006). Sales manipulation is defined as managers' attempts to temporarily increase sales during the year by offering price

discounts or more lenient credit terms. The cash inflow per sale, net of discounts, from these additional sales is lower as margins decline. The lower margin due to the price discounts causes production costs relative to sales to be abnormally high. These are essentially price discounts and lead to lower cash inflow over the life of the sales, as long as suppliers to the firm do not offer matching discounts on firm inputs. In general, sales management activities to lead to lower current-period CFO and higher production costs than what is normal given the sales level.

Following Roychowdhury (2006), normal cash flow from operations is a linear function of sales and change in sales in the current period. To estimate the model, we run the following cross-sectional regression:

$$CFO_t/At_{-1} = \alpha_0 + \alpha_1 (1/A_{t-1}) + \alpha_2 (S_t/A_{t-1}) + \alpha 3 (\Delta S_t / A_{t-1}) + \varepsilon t$$

where At is the total assets at the end of period t, St the sales during period t and ΔS_t = St – St_{-1}. For every firm-year, abnormal cash flow from operations is the actual CFO minus the "normal" CFO calculated using estimated coefficients from the corresponding industry year model and the firm-year's sales and lagged assets. Abnormal level = Actual level – Normal Level.

To manage earnings upward, managers of manufacturing firms can produce more goods than necessary to meet expected demand. With higher production levels, fixed overhead costs are spread over a larger number of units, lowering fixed costs per unit. As long as the reduction in fixed costs per unit is not offset by any increase in marginal cost per unit, total cost per unit declines. This implies that reported COGS is lower, and the firm reports better operating margins. Nevertheless, the firm

incurs production and holding costs on the over-produced items that are not recovered in the same period through sales. As a result, cash flows from operations are lower than normal given sales levels. Ceteris paribus, the incremental marginal costs incurred in producing the additional inventories result in higher annual production costs relative to sales.

The model for normal COGS is estimated as:

$$COGS_t/A_{t-1} = \alpha_0 + \alpha_1 (1/A_{t-1}) + \alpha_2 (S_t/A_{t-1}) + \varepsilon_t$$

The model for 'normal' inventory growth using the following regression:

$$\Delta INV_t/A_{t-1} = \alpha_0 + \alpha_1 (1/A_{t-1}) + \alpha_2 (\Delta S_t / A_{t-1}) ++ \alpha_3 (\Delta S_{t-1} / A_{t-1}) \varepsilon_t$$

where ΔINV_t is the change in inventory in period t.

Production costs as:

$$PROD_t = COGS_t + \Delta INV_t.$$

Using (2) and (3), normal production costs from the following industry-year regression:

$$PROD_t/A_{t-1} = \alpha_0 + \alpha_1 (1/A_{t-1}) + \alpha_2 (\Delta S_t/A_{t-1}) + \alpha_3 (\Delta S_t / A_{t-1}) + \alpha_4 (\Delta S_{t-1} / A_{t-1}) \varepsilon_t$$

Discretionary expenses be expressed as a linear function of contemporaneous sales, similar to COGS.

The relevant regression would then be:

$$DISEXP_t/A_{t-1} = \alpha_0 + \alpha_1 (1/A_{t-1}) + \alpha_2 (S_{t-1}/A_{t-1}) + \varepsilon_t$$

where DISEXPt is discretionary expenses in period t. Discretionary expenses as

DisExp = R&D + Advertising + SG&A expenses

MEASUREMENT ACCRUAL MANIPULATION

Signed abnormal accruals are used rather than absolute (unsigned) abnormal accruals (Hribar and Nichols, 2006). A cross-sectional Jones (1991) model is not practical for the calculation of abnormal accruals with international data because the number of industry observations per country can be quite small, and this may explain, at least in part, why Jones-type abnormal accruals perform unreliably in international settings (Wysocki 2004; Meuwissen et al. 2005). We avoid this problem by using a linear expectation model adapted from DeFond and Park (2001) which uses a firm's own prior year accruals in calculating the expectation benchmark. Specifically, expected accruals are based on a firm's prior year ratio of current accruals to sales, and the prior year's ratio of deprecation expense to gross property plant and equipment (hereafter PPE). Another benefit of this approach is that we also implicitly control for cross-country differences in accounting standards by using a firm as its own control to compute abnormal accruals. Therefore abnormal accruals are contextualized relative to the specific accounting standards of a particular country.

Using data from OSIRIS file, predicted accruals are calculated as:

Predicted accruals = {[$Sales_t$ x (current $accruals_{t-1}$ / $sales_{t-1}$] + gross PPE_t x (depreciation$_{t-1}$ /gross PPE_{t-1}/total $assets_{t-1}$].

Abnormal accruals = firm's actual total $accruals_t$ - predicted total $accruals_t$.

Total accruals in year t are calculated as follows:

Total accruals = {Earnings before extraordinary items – Operating cash flows}/ total assets$_{t-1}$

Current accruals = change in non-cash working capital = Δ[total current assets –

cash and short term investments – treasury stock shown as current assets – Δ[total current liabilities – total amount of debt in current liabilities – proposed dividends].

MEASUREMENT OF INVESTOR PROTECTION

We begin with a descriptive country cluster analysis, which groups countries with similar legal and institutional characteristics. We use multiple investor protection measures are:

1. Outside Investor Right; is an aggregate measure of minority shareholder rights and ranges from zero to five.

2. Disclosure requirements.

3. Important of equity market; is measured by the mean rank across three variables used in La Porta et al. (1997). Each variable is ranked such that higher scores indicate a greater importance of the stock market.

4. Legal enforcement; is measured as the mean score across three legal variables used in La Porta et al (1998). Three variables range from 0 to 10.

Cluster analysis is based on four measurement of investor protection. Then we compare score earnings management between clusters. We use accrual manipulation and real activities to measure earnings management activities.

To test H1a we compare abnormal accrual between clusters. To examine more explicitly which institutional factors are the determinant of earnings management, we undertake regression analysis based on model 1 to test H1:

Model 1: $AB\_ACCR_{it} = \beta 0 + \beta 1\ LAW + \beta 2\ OUTSIDE\_RIGHT + \beta 3\ DIS\_REQ + \beta 4 LEG\_ENF + \beta 5\ IM + e_{it}$ …………………………………………….(1)

To test H2a- H2b, we use model 2a-b:

Model 2a: AB_CFO = β0 + β1 LAW + β2 OUTSIDE_RIGHT + β3 DIS_REQ +

β4LEG_ENF + β5 IM + eit ……………………………………………...(2)

Model 2b: AB_Prod = β0 + β1 LAW + β2 OUTSIDE_RIGHT + β3 DIS_REQ +

β4LEG_ENF + β5 IM + eit ……………………………………………(3)

where:

AB_ACCRit = abnormal accruals scaled by lagged total assets for firm i in year t.

AB_CFO = abnormal cash flow

AB_DiscExp = abnormal discretionary expenses

AB_Prod = abnormal production cost

INVPRO = proxies of investor protection, measured six ways:

1. Outside_Right = outside investor right

2. DIS_REQ = index of disclosure requirement

3. LEG_ENF = legal enforcement.

4. IM = Important of equity market.

Because abnormal cash flow, discretionary expenses and production cost are more aggressive in suspect firm (firm close to zero earnings), we conduct sensitivity analysis to regress model 1 and 2 in full sample (suspect & non suspect firm).

RESULTS

Descriptive Statistics

Our data obtained from OSIRIS database, which contains financial data from annual reports of publicly traded around the world. Only industrial companies are included in empirical analysis. Each firm must have income statement and balance sheet

information for estimation period. The final sample consists of 5,931 firm-year observations, across 7 countries for fiscal years 1993-1997.

Table 1 panel A presents the number of firm-year observation per country as well as descriptive statistic for three individual earnings management measure. Panel B present institutional characteristics of each country

Table 1: Descriptive statistics for earnings management and institutional characteristics

Panel A. Country score for earnings management measures

Countries	Firm-Years	Abn CFO	Abn Prod Cost	Abn Acrual
Korea	1141	0,0012	-0,1281	0,0834
Japan	2785	0,0005	-0,0003	0,0631
Malaysia	792	0,0315	-0,0002	0,0561
India	566	-0,0269	0.0000	0,1201
Indonesia	129	0.0000	0.0000	0,0788
Hongkong	101	0.0002	0.0000	0,144
Singapore	398	0.0001	0,0055	0,0995

Panel B. Institutional characteristics of the sample countries

Countries	Outside Investor Right	Legal enforcement	Important Equity Market	disclosure Index	cluster (1:high, 3 low)
Korea	2	5.6	11.7	62	3
Japan	4	9.2	16.8	65	2
Malaysia	4	7.7	25.3	76	1
India	5	5.6	14	57	3
Indonesia	2	2.9	4.7	na	3
Hongkong	5	8.9	28.8	69	1
Singapore	4	8.9	28.8	78	1

Panel A of table 1 provides descriptive statistics for three individual earnings management measures. The three individual earnings management measures

exhibit striking differences across countries. The statistics of the mean abnormal CFO and abnormal production cost show that earnings management with real activity manipulation aggressive in economies with high investor protection such as Singapore, Hongkong compared to in economies with low investor protection such as Korea, India. The mean abnormal accrual is high in Singapore compared to Japan.

Result Earnings management with real activities manipulation

Table 2 presents descriptive statistics comparing suspect firm-year to the full sample. Firms that just meet the zero earnings (suspect firm) are probably try to meet the zero target earnings through real activities manipulation. Suspect firm-years have a lower mean of abnormal low CFO than non suspect firm (-0.0031 versus 0.0023). Mean of abnormal production cost is higher for suspect firm compared to non suspect firms (0.1388 versus -0.0074).

Table 2: Descriptive statistics comparing suspect firm-year to rest of the sample

	Suspect firm year	Non suspect firm	Rest of the sample
Full sample 5,931 firm-years with 273 suspect firm-year			
	means	means	means
Net Income/ TA	0,0029	0,0378	0,362
Abn Accruals	-0,0884	-0,0675	-0,0685
Abn CFO	-0,0031	0,0023	0,0021
Abn Prod	0,1388	-0,0074	-0,0006

Estimation model

Table 3 reports the regression coefficients for some of the key regression used to estimate 'normal level'. We estimate using the entire sample of 5,931 firm-years. The

coefficient generally as predicted by Roychowdhury (2006). The coefficient of CFO on sales change actually positive, for all country, and marginally significant, indicating that conditional on contemporaneous sales, a higher change in sales implies higher CFO.

*signifikan at level 10%

This table reports the estimated parameters in following regression:

$CFO_t/A_{t-1} = \alpha_0 + \alpha_1 (1/A_{t-1}) + \alpha_2 (S_t/A_{t-1}) + \alpha3 (\Delta S_t / A_{t-1}) + \varepsilon t$

$PROD_t/A_{t-1} = \alpha_0 + \alpha_1 (1/A_{t-1}) + \alpha_2 (\Delta S_t/A_{t-1}) + \alpha3 (\Delta S_t / A_{t-1}) + \alpha4 (\Delta S_{t-1} / A_{t-1})\ \varepsilon t$

Comparison of suspect firm years with non suspect firm-years and the rest of sample

If firm-year that report profit just above zero undertake activities that adversely affect their CFO, then abnormal CFO for these firm-years, should be negative compared to the rest of sample. To test this, we estimate the following regression:

Y = α + β1(Net Income) + β2(Suspect_NI) + ε ……………(4)

The dependent variable, Y, is abnormal CFO and abnormal production cost in period t. Suspect_NI is an indicator variable that is set equal to 1 if firm-years belong to the earnings category just right of zero, and zero otherwise.

Table 4: Comparison suspect firm years with non suspect sample.

	Abnormal CFO	Abnormal Production Costs
Intercept	0,022 (2.614)	-0.002 (-0.200)
Net Income	0,008* (1.061)	-0.269* (-5.518)
Suspect_NI	-0,217* (-5.552)	0.142* (3.246)

The first column in table 4 provides evidence that abnormal CFO is unusually low for suspect firm years, consistent with Roychowdhury's model. When dependent variable is CFO in regression (4), the coefficient on SUSPECT_NI is negative (-0,217) and significant at level 10%. Suspect firm-years have abnormal CFO is lower than non suspect firm.

When Y is abnormal production cost, the coefficient on SUSPECT_NI is positive 0.142. The coefficient indicates that the mean abnormal production cost of suspects firm-years are larger 14.2% of assets than the mean across the rest of sample.

Descriptive cluster analysis

To provide descriptive evidence on systematic pattern in earnings management method across group of countries with similar institutional characteristics, we begin with cluster countries based on institutional characteristics (Leuz, 2003). The first cluster is characterized by large stock markets, low ownership concentration, extensive outsider right, high disclosure, and strong legal enforcement. The second and third cluster show markedly smaller stock markets, higher ownership concentration, weaker investor protection, lower disclosure level, and weaker enforcement, with the distinction that countries in the second cluster have significantly better legal enforcement than countries in the third cluster. Based on institutional characteristics, we refer countries in the first cluster as 'high investor protection economies'. The countries in the second and third cluster

To provide descriptive evidence on the systematic patters of earnings management method across cluster, we use ANOVA analysis to compare aggressiveness of real activity manipulation and accrual manipulation across group of countries.

Table 5 shows the difference of aggressiveness earnings management method across cluster.

Table 5:Pervasiveness of earnings management by cluster

	Cluster 1 (high investor protection)	Cluster 2	Cluster 3 (low investor protection)
Abnormal CFO	-0.0075	0.0005	0.0193
Different between cluster	F: 8.753	Sign: 0.000	
Abnormal Production Cost	0.0015	-0.0003	-0.0757
Different between cluster	F: 69.443	Sign: 0.000	
Abnormal Accrual	-0.1013	-0.0631	-0.0533
Different between cluster	F: 2.795	Sign: 0.061	

Table 5 shows that the differences between cluster's average earnings management are statistically significant. High investor countries (cluster1) exhibit lower level of earnings management with accrual manipulation than low investor protection countries. This finding consistent with leuz (2003) that earnings management is expected to decrease in investor protection because strong protection limits insider's ability to acquire private control benefit, which reduces incentives to mask firm performance. But earnings management with real activity management is higher in economies with strong investor protection. Real activity manipulation can be detected by investigate the pattern of CFO and production cost. Deviation from normal level of CFO and Production cost are termed abnormal CFO and abnormal production cost. The abnormal CFO is lower in economies with high investor protection rather than in low investor protection. Abnormal production cost is higher in economies with high investor protection than in low investor protection.

Suspect firm year more aggressive in real activity manipulation, we conduct sensitivity analysis to compare differences in earnings management activity between clusters for suspect firm year. Thus, our results are sensitive to sample selection.

Table 6: Pervasiveness of real activity manipulation suspect year firm by cluster

Cluster	Abnormal CFO	Abnormal Production Cost
1 (high investor protection)	0.0130	0.0189
2	-0.0255	0.0556
3 (low investor protection)	0.0342	-0.2067
Differences between clusters	2.369	47.419
	(0.096)	(0.000)

Table 6 shows that suspect firm-years in cluster high investor protection exhibit abnormal low CFO and abnormal high production cost comparing to cluster low investor protection. This result is consistent with previous analysis.

In summary, the evidence earnings management with real activity manipulation is higher in economies with high investor protection rather than in economies with low investor protection. Earnings management with accrual manipulation is more aggressive in economies with low investor protection than in economies with high investor protection.

The Role of Investor Protection: multiple regression analysis

The previous analysis shows that pervasiveness of earnings management with real activities manipulation or accrual manipulation is systematically related to a country's institutional characteristics. A key question is which institutional factors are primary determinant of earnings management's method choice. We posit that better investor protection result in less earnings management with accrual manipulation because accrual manipulation is easy to detect and hence lower incentives to conceal firm performance with accrual manipulation. Our multiple regression examines the relation between earnings management's method choice and investor protection.

Table 7: Earnings management's method choice and investor protection

	Abnormal accrual	Abnormal CFO	Abnormal Production Cost
Constant	1.974 (4.023)	0.392 (1.511)	-0.725 (-2.259)
Outside investor right	-0.082* (-3.627)	-0.006 (-0.874)	0.059* (6.709)
Legal enforcement	-0.013 (-1.318)	-0.009* (-2.517)	0.009* (2.191)
Important equity market	0.013* (1.806)	-0.006* (-2.309)	-0.006* (-1.879)
Disclosure index	-0.036* (-4.350)	-0.001* (-0.238)	0.007* (0.044)
R^2			

Our multiple regression results presented at column 1 of Table 7 report regression analysis using abnormal accrual as the dependent variable. Results show that outside investor right, legal enforcement and disclosure index exhibit a significant negative association with abnormal accrual. The higher level of investor protection will reduce aggressiveness earnings management with accrual manipulation. All variables consistent with prediction, with the exception important of equity market variables.

We attempt to provide evidence on hypothesis that investor protection is positively related to earnings management with real activity manipulation. We use abnormal low cash flow from operation and abnormal high production cost as a measure earnings management with real activity manipulation. The results presented in column 2 of table 6 show that investor protection and abnormal low CFO exhibit negative association as predicted by our hypothesis. Results show that legal enforcement, important equity market and disclosure index exhibit a significant negative association with abnormal low CFO. The higher outside investor right, legal enforcement and disclosure index, the lower level abnormal CFO. The result also support that investor protection and abnormal high production cost are positively related. Column 3 of table 6 show that outside investor right, legal enforcement, and disclosure index exhibit a significant positive association with abnormal production cost.

In summary, the multiple regression results are consistent with the hypothesis that investor protection affects earnings management method choice. In economies with high investor protection, it is too costly to manage earnings with accrual manipulation. The cost of detection of accrual manipulation is high because essentially, a manager can borrow earnings from future periods, through the acceleration of revenues or deceleration of expenses, in order to improve current earnings. The cost of detection bears a one-to-one

cost of earnings reduction in the future; future-period earnings will be mechanically lower by the net income that was accelerated to current earnings. The other type of earnings management can occur through the manipulation of real activities, such as providing price discounts to increase sales and cutting discretionary expenditures, such as R&D, to manage earnings. Such actions can increase revenues or net income, but they are also costly. For example, cutting R&D spending to manage earnings may result in the loss of future income related to the forgone R&D opportunities. On the other hand, because the manipulation of real activities is not a GAAP violation, this earnings management tool is expected to have a lower cost of detection than accrual management. So we argue that in economies with high investor protection, manager prefer to use real activity manipulation to mask firm performance. The result of our analysis consistent with our prediction.

Limitation and Conclusion

This paper documents systematic differences in the earnings management method across countries with different level of investor protection. We perform ANOVA and multiple regression analysis to test differences earnings management's method across cluster countries based on institutional characteristics. The analysis suggest that in economies with high investor protection earnings management with accrual manipulation is lower than in economies with low investor protection.

Prior research has provided evidence on managers' incentives for earnings management and earnings management more aggressive in countries with low legal enforcement but there is relatively little evidence on what manager's method to manage earnings in different legal environment. In addition, prior research used accrual manipulation to measure earnings management but actually management have flexibility to manage earnings with accrual manipulation, real activities manipulation or classification

shifting. Earnings management through accrual manipulation is more likely to draw auditor or regulator scrutiny than real decisions about pricing and production. So this paper attempts to provide evidence does investor protection determine manager choice between real activities manipulation versus accrual manipulation when they have the flexibility to engage both. We expect that earnings management through accrual manipulation decreases in legal protection because when investor protection strong, accrual manipulation will decrease because it is easy to detect. But in strong investor protection's countries, earnings management through real activities manipulation more aggressive because real activities manipulation can be subjective, auditor might be limited in their ability to verify the appropriate classification. In countries with weak investor protection, manager have great discretionary to manage earnings with both accrual manipulation and real activity manipulation.

Consistent with the hypothesis, the regression result show that accrual manipulation is negatively associated with quality of outside investor right, legal enforcement, and quality of disclosure. Real activities manipulation is positively association with outside investor right, legal enforcement and quality of disclosure. This finding highlight that level of investor protection determine management's choices on earnings management's method.

The limitation of this study: we are not include abnormal discretionary expenses to measure real activity manipulation because unavailable data. We only measure the pattern of abnormal CFO and abnormal production cost. We argue that pattern abnormal discretionary expenses have been captured at the pattern of abnormal CFO. Reducing discretionary expenses have a positive effect on abnormal CFO in the current period, possibly at risk of lower cash flow in the future.

THE EFFECT OF MAJORITY SHAREHOLDER OWNERSHIP ON REAL EARNINGS MANAGEMENT: A KOREAN PERSPECTIVE

Jai-Min Goh, Yonsei University
Ho-Young Lee*, Yonsei University

Hanyang University

Abstract: This study investigates the effect of corporate ownership structure on real earnings management in order to determine whether there is a conflict or alignment of interests of majority and minority shareholders. Although majority shareholders may use the discretion in accounting for their private benefits, they are expected to be more careful to managers' myopic activity, i.e. real earnings management. This is because real earnings management has a more direct effect on not only firm's operating performance but also majority shareholders' own wealth than does accruals-based earnings management. Furthermore, according to prospect theory, majority shareholders may be more sensitive to upward earnings management that results in loss in their future wealth than downward real earnings management. We find that real earnings management significantly decreases with large ownership by majority shareholders only in the upward earnings management bracket. On the contrary, in the downward and ambiguous earnings management brackets real earnings management is not different regardless of the level of majority shareholders' ownership. The result with upward earnings management bracket suggests that majority shareholders with large ownership play a positive role in maintaining firm value, and ultimately for both majority and minority shareholders' wealth. In addition, we verify that even though upward earnings management lowers long-term performance, majority shareholders with large ownership mitigate this negative effect. Our finding supports the convergence-of-interests hypothesis and prospect theory, providing some insights on this controversial issue by using real earnings management instead of accruals-based earnings management.

Keywords: corporate ownership, majority shareholders, real earnings management, convergence-of-interests hypothesis.

I. INTRODUCTION

This study examines how majority shareholder ownership impacts real earnings management in Korea where majority shareholders heavily influence management decisions.[21] Our major purpose for investigating the effect of ownership structure on real earnings management is to determine whether majority shareholders act in ways detrimental to or in the interests of minority shareholders.[22]

As to the role of majority shareholders, whether the convergence-of-interests or the expropriation-of-the-minority-shareholders hypothesis is correct has been the subject of controversy in East Asian countries. According to the conventional perspective on the agency problem, majority shareholders play an active role in monitoring managers (Jensen and Meckling, 1976). They do this because their wealth is more influenced by the firm's operating results, and they are in an easier position to obtain information about managers' decision as their ownership increases. In contrast, the latter perspective is based on the notion that majority shareholders act in ways detrimental to minority shareholders by transferring the wealth of minority shareholders to themselves (La Porta et al., 1999). This hypothesis posits that if majority shareholders can easily control managers' activities and exploiting the minority shareholders, they will attempt to transfer minority shareholders' wealth to themselves.[23] These arguments are still being debated among researchers interested in corporate governance in East Asia.

---

[21] Johnson et al. (2000) argued that managers' business decision is actually affected by majority shareholder in East Asia. Similarly, major agency problem in these countries is not between shareholders and managers but between majority and minority shareholders (Claessens et al. 2000). Korean studies also indicated this problem. For example, Jung et al. (2002) stated that majority shareholders have ownership enough to govern management decision in Korea. An et al. (2002) also showed evidence that majority shareholders in Korea have the right to control management decisions.

[22] Following Article 2 of the Korean Securities and Exchange Act, majority shareholder ownership in this study is computed as the proportion of the total numbers of shares held by the largest shareholder and his/her affiliated persons, affiliated firms, or executives of affiliated firms.

[23] These opposing claims have also been made in the context of Korea. Choi and Kim (2001) found that management tends to manage earnings to a greater extent as majority shareholder ownership decreases. However, Park (2003) showed that majority shareholders tend to transfer the wealth of

Thus, we provide additional evidence to settle this controversy. It is crucial to determine the behavior of majority shareholders with real earnings management in East Asian countries, including Korea, because companies in these countries are not considered to be fully independent of majority shareholders. If majority shareholders serve only their own selfish interests and even exploit minority shareholder's wealth, they should be more regulated. In contrast, if they help increase firm value and eventually the wealth of other investors in the firm, their positive role has to be reassessed. Majority shareholders would be careful in altering actual management decisions because real earnings management changes their own wealth and firm value in the long-run. This behavior would become more pronounced as the proportion of majority shareholders' ownership becomes larger.

This study differs from prior studies in the following aspects. First, this study analyzes the effect of corporate ownership on real earnings management, while most prior studies have examined the effect of corporate ownership structure on accruals-based earnings management through discretionary accruals. Burgstahler and Dichev (1997) suggested that real earnings management is more important than accruals-based earnings management, because the former is characterized by managers' myopic earnings manipulation in actual management decisions. Following Roychowdhury (2006) and Cohen et al. (2008), we used real earnings management to analyze managers' opportunistic behaviors to overcome the limits of accruals-based earnings management. In this study, abnormal cash flow from operation, abnormal production cost, and abnormal discretionary expenses reflect managers' real earnings management. While accruals-based earnings management only results in accruals reversal, real earnings management distorts resource allocation and worsens actual operating performance in the long-run.

minority shareholders to themselves as their ownership increases.

Thus, real earnings management more realistically tests whether the interests of majority and minority shareholders are aligned. Second, unlike previous studies, we examine the relationship between majority shareholders' ownership and real earnings management in various brackets that have different earnings management incentives. Prior studies ignored the effects of different underlying incentives on earnings management (Klassen, 1997; La Porta et al., 1999; Choi and Kim, 2001; Park, 2003). As prospect theory assumes that investors' sensitivities to loss are higher, we expect that majority shareholders' monitoring would be stronger in the upward earnings management incentive bracket.

The results of this study are as follows. First, in the whole sample, we found no systematic association between the proportion of majority shareholder ownership and real earnings management. Second, in the upward earnings management incentive bracket there was a significantly negative relationship between majority shareholders' ownership and real earnings management. In contrast, in the downward and ambiguous earnings management incentive brackets, majority shareholders' ownership was generally not associated with real earnings management. Lastly, while following operating performance declines in the upward real earnings management bracket, majority shareholders with higher ownership attenuate this negative result. These empirical results suggest that the interests of both majority and minority shareholders are aligned because upward real earnings management is curtailed as the proportion of majority shareholders' ownership rises, supporting the convergence-of-interests hypothesis. The results are also consistent with prospect theory in that the behavior of the majority shareholders is asymmetric between loss and profit.

The remainder of this paper is organized as follows. A theoretical background and overview of prior studies are provided in Section II; hypotheses are presented in Section III; research methods and data collection are described in Section IV; and the empirical

results are presented in Section V. Finally, the conclusions and limitations of the study are presented in Section VI.

II. BACKGROUND AND LITERATURE REVIEW

2.1 Corporate Ownership Structure and Earnings Management

Claessens et al. (2000) found that companies in East Asian countries do not have a clear separation between control and management of majority shareholders. In this unclear separation, two hypotheses to explain the agency problem between majority and minority shareholders have been proposed. The first hypothesis is the convergence-of-interests hypothesis, which claims that majority shareholders will not pursue activities that reduce the wealth of a company because they have greater interests as shareholders when the proportion of ownership held by majority shareholders is higher. Therefore, there will be a convergence of the interests of majority and minority shareholders. The second hypothesis is the expropriation-of-the-minority-shareholders hypothesis, which expresses the exact opposite viewpoint. It claims that there is an information asymmetry between majority and minority shareholders, and that a company acts in detriment to the wealth of minority shareholders to maximize that of majority shareholders. Although there are evidences for both hypotheses, neither of these two hypotheses has received unequivocal support.

Examining the convergence-of-interests hypothesis, Watts and Zimmerman (1986) found that owner-management with smaller equity has an incentive to act in opposition to the company's value maximization to pursue private profit. Klassen (1997) found that a higher level of majority shareholder ownership lowers the financial reporting incentive and increases the tax reporting incentive. Therefore, he concluded that profit from property disposition is reduced when majority shareholder ownership increases if a company has a

higher tax rate. In addition, discretionary expenses have a negative relationship to ownership concentration (Warfield et al., 1995). In Korea, Choi and Kim (2001) found that a company with lower majority shareholder ownership also has a larger absolute value of discretionary accruals. Based on this finding, they claimed that management has more incentive for opportunistic earnings management when the investment of majority shareholders is small.

There is also evidence supporting the expropriation-of-the-minority-shareholders hypothesis. La Porta et al. (1999) analyzed the corporate ownership structure of large companies from 27 countries and reported that controlling shareholders act opportunistically against the interests of minority shareholders to increase their own utility as a company's ownership structure becomes more concentrated. In Korea, Park (2003) showed that there is a positive relationship between majority shareholder ownership and discretionary accruals. He concluded that the expropriation-of-the-minority-shareholders hypothesis is supported.

2.2 Real Earnings Management

Schipper (1989) defined earnings management as managers' intentional adjustment to gain private benefit. Accruals-based earnings management involves adjusting net income by changing accounting methods without changing actual operations while real earnings management involves the management of operational activities (Roychowdhury, 2006). Graham et al. (2005) argued that managers prefer real earnings management because it is safer than accruals-based earnings management by not getting as much attention from regulatory bodies and external auditors as accruals-based earnings management. For example, management can influence net income by adjusting research and development (R&D) expenses or advertisement expenses. Moreover, managers can boost sales by pricing down products or selling off securities. In this way,

203

real earnings management directly influences companies' actual operations. Real earnings management undertaken to increase current accounting numbers, however, results in damaging long-term firm value. Therefore, it costs much more compared to accruals-based earnings management.

Most prior studies on earnings management have focused on accruals, while real earnings management has been neglected. Existing studies on real earnings management focus mostly on investment or finance activity rather than operating activity (see, for example, Dechow and Sloan, 1991; Bartov, 1993; Bens et al., 2002; Bushee, 1998). Roychowdhury (2006) suggested estimation models to derive proxies for real earnings management, which include abnormal cash flow from operations (ACFO), abnormal production costs (APC), and abnormal discretionary expenses (ADE). He found evidence that companies manage earnings utilizing ACFO, APC, and ADE to meet earnings benchmark. Cohen et al. (2008) examined whether there was any change in earnings management behavior before and after the Sarbanes-Oxley Act (SOX hereafter). They showed that real earnings management was higher in post-SOX period than pre-SOX period. They argued that companies preferred real earnings management to accruals-based earnings management under the strict accounting regulations of SOX.

2.3 Earnings Management across Incentives' Brackets

Burgstahler and Dichev (1997) examined the distribution of earnings levels and showed that an exceptionally small number of companies was positioned in the section slightly less than zero and an abnormally large number of companies was found in the section slightly more than zero. Based on this result, they concluded that companies manage their earnings to avoid reporting losses.

Earnings management is not always performed to increase profit. Prior studies have shown that not only upward but also downward earnings management is performed to

increase earnings in a later period and smooth income according to the circumstances that a company faces. DeFond and Park (1997) showed that management who tries to report stable income flow reduces (or increases) profit through downward (or upward) earnings management when the current year's income is high (or low).

Healy (1985) found that managers try to lower accounting income if reported earnings exceed a certain threshold at which their bonuses can be paid at the maximum. Managers may also lower reported earnings when it does not reach a minimum threshold to deposit current earnings for future bonuses (Healy 1985). The direction of earnings management may correspond to managers' income smoothing incentives. However, Gaver et al. (1995), re-verifying the results of Healy (1985), reported that companies experience upward earnings management when profit is less than the minimum incentive level.[24]

To summarize prior studies, earnings management incentives move in different directions according to the level of earnings. Frank and Rego (2006) showed that earnings management incentives differ according to the circumstances of the company. They investigated how management uses the valuation allowance of deferred corporate taxes for earnings management. In particular, they divided earnings management incentive into three brackets: (1) profit before earnings management slightly smaller than zero, (2) profit before earnings management much larger than zero, and (3) profit before earnings management much less than zero. They also demonstrated that earnings management moves in different directions according to earnings management incentives.

---

[24] Two studies examined situations with low reported earnings: Gaver et al. (1995) reported results identical to incentives for nominal zero earnings, while Healy (1985) supported the big bath argument. The results from prior studies on the two incentives are generally mixed.

III. HYPOTHESES DEVELOPMENT

Earlier studies have shown that majority shareholders sometimes act against the interests of minority shareholders, and that this behavior changes according to the corporate ownership structure. The convergence-of-interests hypothesis claims that majority shareholders will not pursue activities that reduce the value of a company because they have a vested interest as shareholders in its success, even more so as their proportion of ownership increases. However, the expropriation-of-minority-shareholders hypothesis, which emphasizes information asymmetry between majority and minority shareholders, argues that companies tend to act in detriment to the wealth of minority shareholders as the proportion of majority shareholders grows.

These two opposite hypotheses can be applied only to accruals-based earnings management. That is, majority shareholders may use discretion in their accruals to overstate short term performance and deceive minority shareholders with information asymmetry between them. On the other hand, if the proportion of majority shareholders ownership increases, they pay more attention to the effectiveness of the business to improve longer term performance. Klassen (1997) also suggested that the more shares majority shareholders hold, the more interested in cash flows rather than reported income.

However, referring to real earnings management, it is irrational for majority shareholders to allow real activity manipulation to raise current period net income, because it will eventually impair their own wealth as well. After upward real earnings management, majority shareholders may suffer from a bigger loss in their own wealth than minority shareholders. Therefore, we expect that real earnings management will decrease when the proportion of ownership held by majority shareholders is higher. Thus, our first hypothesis, stated in an alternative form, is as follows:

206

Hypothesis 1: *Companies with higher proportions of majority shareholder ownership reduce real earnings management.*

Since Kahneman and Tversky (1979) many researchers have explained investors' behavior with the prospect theory. Shefrin and Statman (1985), for example, found that investors tend to hold the stock when price declines while they sell the stock early when return is positive. They defined this asymmetric phenomenon as a disposition effect and argued that it came from investors' greater tendency to avoid losses than to realize profits. This tendency implies an increase in disutility from experiencing wealth decline is greater than that in utility from earnings profits. This asymmetric phenomenon is commonly described as the prospect theory.

The prospect theory can be applied to majority shareholders' behavior toward real earnings management. Real earnings management can be divided into upward and downward earnings management. Prior studies have reported that upward real earnings management results in downturns in future performance. In contrast, downward real earnings management does not impair long term operating performance and may in fact improve future performance while sacrificing reported earnings in the short-run. Gunny (2005) found that abnormal business decisions have adverse effects on operating performance. Mizik and Jacobson (2007) found that companies using upward real earnings management showed significant decreases in stock price after they raised funds.

Majority shareholders would be more interested in the long-term value of a company since their wealth is more affected by firm value than minority shareholders. Thus, consistent with the prospect theory, majority shareholders with larger ownership would be more sensitive to upward real earnings management resulting in worse operating performance in later periods. On the other hand, although there is an income smoothing incentive that might lead to downward earnings management, the majority shareholders

with larger ownership are expected to be less interested in it. This is because downward real earnings management is likely to result in a greater operating performance in the long-run. We, therefore, hypothesize that avoidance of upward real earnings management will be stronger than that of downward real earnings management when majority shareholders have higher levels of ownership.

****

</center>

This study utilizes three earnings management incentive brackets (Frank and Rego, 2006), as shown in FIGURE 1: (1) upward earnings management, (2) downward earnings management, and (3) ambiguous earnings management. Following Burgstahler and Dichev (1997) and Phillips et al. (2003), we first assume that companies with reported earnings slightly greater than zero have a great incentive toward upward adjustment to avoid a deficit, and therefore classify these companies in the upward earnings management bracket. Second, companies with earnings much greater than zero have a motivation for income smoothing, and are therefore classified as being in the downward earnings management bracket. Third, companies with earnings much less than zero might be tempted not only to implement a big bath, which reserves earnings to improve future, but also to reduce loss. Therefore, these companies are classified as being in the ambiguous earnings management bracket, with mixed upward and downward earnings management incentives. Among these three brackets, in the upward earnings management incentive bracket majority shareholders monitor managers' opportunistic activities more closely to protect their own wealth as the proportion of ownership rises.

Hypothesis 2a: *In the upward earnings management incentive bracket, real earnings management is smaller when the majority shareholder*

> *ownership is high compared to low majority shareholder ownership.*

Hypothesis 2b: *In the downward earnings management incentive bracket, real earnings management is indifferent between high majority shareholder ownership and low majority shareholder ownership.*

Hypothesis 2c: *In the ambiguous earnings management incentive bracket, real earnings management is indifferent between high majority shareholder ownership and low majority shareholder ownership.*

IV. RESEARCH DESIGN AND DATA COLLECTION

4.1 Real Earnings Management Estimation Model

Real earnings management can be divided into three categories: (1) sales, (2) production, and (3) expenses. First, from a sales perspective, management can execute abnormal promotional events and discounts and can ease credit policy to increase the accruals-based accounting profit of the current period. However, although offering discounts will increase the accounting profit of the current period, it may damage long-term brand power and increase bad debt in the future. Second, from a production perspective, management can increase production to lower fixed overhead costs per unit, which in turn will decrease the cost of goods sold. Although this can increase accruals-based accounting earnings in the short term, the value of the company will decrease due to inventory maintenance costs and deterioration. Third, discretionary expenses are directly connected to profit and loss. Therefore, management can reduce the current period's advertising expenses, R&D expenses, education and training expenses, and fringe benefit. Although this might improve the current term's profit, it will reduce long-term brand awareness and quality of product and result in the drain of talents, thereby decreasing the quality of employees.

These changes in management activity can be measured by three variables: (1) cash flow from operations (CFO), (2) production costs (PC), and (3) discretionary

expenses (DE). CFO is affected by changes in all three categories mentioned above.

Discounts and increased credit sales will reduce cash flow compared to sales with regular

prices and credit policies. Moreover, increased production will increase labor costs,

material costs, and cash expenses, which in turn will reduce cash flow from operations.

Although cost reduction reduces cash expenses, which is expected to increase cash flow,

cost reductions in sales management or research and development can also reduce sales

in the current term. Therefore, increased cash flow from reduced costs leads to decreased

cash flow due to a reduction in sales. From a sales and production points of view, CFO will

be reduced per regular sales. From a cost reduction standpoint, CFO will not increase or

will increase only slightly. Therefore, even though cash flow could increase or decrease, it

is rational to expect a general decrease in cash flow because the effect from sales and

production is great.

PC can be divided into two categories: cost of goods sold (COGS) and inventory.

COGS will be reduced because of reduced fixed costs. However, it can increase as sales

decrease. Moreover, management can increase production until the cost of inventory does

not exceed the amount of decreased COGS if attempting earnings management. In

addition, DE will decrease as research and development expenses and advertisement

expenses decrease.

We adopted the Roychowdhury (2006) model to estimate real earnings

management: abnormal cash flow from operations (ACFO), abnormal production costs

(APC), and abnormal discretionary expenses (ADE). The abnormal portion of each

variable is calculated by subtracting the estimated value from the actual value. Equations

(1) to (3) are used as estimation models, and were introduced by Roychowdhury (2006)

based on Dechow et al. (1998). Moreover, each model was estimated through cross-

sectional analysis according to industry and year to reflect the characteristics of each industry and year.

$$\frac{CFO_t}{A_{t-1}} = \alpha_0 + \beta_1 \cdot \frac{1}{A_{t-1}} + \beta_2 \cdot \frac{S_t}{A_{t-1}} + \beta_3 \cdot \frac{\Delta S_t}{A_{t-1}} + \varepsilon_t \tag{1}$$

$$\frac{PC_t}{A_{t-1}} = \alpha_0 + \beta_1 \cdot \frac{1}{A_{t-1}} + \beta_2 \cdot \frac{S_t}{A_{t-1}} + \beta_3 \cdot \frac{\Delta S_t}{A_{t-1}} + \beta_4 \cdot \frac{\Delta S_{t-1}}{A_{t-1}} + \varepsilon_t \tag{2}$$

$$\frac{DE_t}{A_{t-1}} = \alpha_0 + \beta_1 \cdot \frac{1}{A_{t-1}} + \beta_2 \cdot \frac{S_{t-1}}{A_{t-1}} + \varepsilon_t \tag{3}$$

where CFO = Cash flow from operations;
DE = R&D + Advertising + Selling, general, and administrative (SG & A) expenses;
PC = Cost of goods sold + Change in inventory;
A = Total assets; and
S = Sales.

In the estimation model, upward earnings management will result in decreased CFO, increased PC, and decreased DE. In order to align the direction of metrics of real activity manipulation with the same direction in equations (4)-(6), we multiply ACFO and ADE by negative one. After this operational manipulation, all the metrics representing real earnings management, namely ACFO, APC, and ADE, are positively related with upward real earnings management. In addition, to capture the effects of real earnings management for all three variables in a single comprehensive measure, we compute a single variable by combining the three individual real earnings management variables. Specifically, we compute REM as the sum of the individual variables, ACFO, APC, and ADE (Cohen and Zarowin, 2008; Cohen et al., 2008).

$$ACFO_t = (-1) \times \text{Residual from the estimation model of equation (1)} \tag{4}$$
$$APC_t = \text{Residual from the estimation model of equation (2)} \tag{5}$$
$$ADE_t = (-1) \times \text{Residual from the estimation model of equation (3)} \tag{6}$$
$$REM_t = ACFO_t + APC_t + ADE_t \tag{7}$$

4.2 Classification of earnings management

Upward earnings management can worsen the future performance of a company, while downward earnings management can improve it. Burgstahler and Dichev (1997), who reported an extraordinarily high frequency of companies with earnings slightly greater than zero, interpreted this phenomenon as a result of upward earnings management in companies trying to avoid reporting losses. This finding may reflect investors' tendency of being more sensitive to bad news as suggested in Shefrin and Statman (1985).

****
Insert FIGURE 2 about here
****

We measured earnings level by dividing the net income (NI) of a total of 6,440 firm-year samples by total assets at the beginning of the period from 1991 to 2007 and then classified these observations by their earnings levels in terms of increments of 0.005 to derive their distribution. As shown in Figure 2, a great asymmetry exists between the companies with earnings slightly greater than zero and those with earnings slightly below zero. There were 69 companies in the earnings bracket of -0.01 to -0.005 and 74 in the bracket of -0.005 to zero, which is considerably lower than the number at the slightly higher earnings level than zero. Specifically, 462 companies were in the bracket of 0 to 0.005, and 485 fell into the bracket of 0.005 to 0.01. This indicates that the two groups of companies divided using the criterion of zero earnings level have considerable differences in the number of group members. Thus, consistent with Burgstahler and Dichev (1997) and Phillips et al. (2003), this supports the idea that companies with NI slightly less than zero report a surplus by using upward earnings management.

We assigned the companies that use upward earnings management to avoid reporting loss to bracket EM1, where the value of NI divided by total assets at the beginning of the current period is slightly greater than zero. More specifically, we defined a

company as an upward earnings management company when it fell into the range of 0 to 0.015.[25]

Healy (1985) demonstrated that downward earnings management occurs when the reported earnings exceed managers' upper incentive boundaries. DeFond and Park (1997) showed that a company implements appropriation of negative discretionary accruals when current performance is strong and appropriation of positive discretionary accruals when performance is weak. Thus, we defined companies with downward earnings management incentives as those with high performance. The bracket EM2, where the value of NI divided by total assets at the beginning of the current period is larger than zero, was populated with companies with an incentive for downward earnings management. Specifically, the brackets with a value of NI divided by total assets at the beginning of the current period over 0.075 were classified as downward earnings management companies.

We examined the earnings management incentive of the companies with earnings much less than zero. The direction of earnings management in these companies is not clear due to the two conflicting incentives, i.e., a big bath incentive that assumes maximum expenditure in the current period with the purpose of improving future performance, and another incentive to minimize the deficit. Healy (1985) posited that downward earnings management occurs when the earnings are so low that they do not reach the lower

---

[25] Post- and pre-managed earnings could be criteria for classifying sample firms with upward earnings management incentives to avoid losses. Theoretically, it seems proper to divide the earnings management incentives according to pre-managed earnings level. However, calculating pre-managed earnings is problematic in that measurement error is a possibility, as is inaccuracy of the computation of the amount of earnings management. Moreover, when variables containing measurement errors are used as independent and dependent variables, results can indicate earnings management even when there is none. In particular, when measurement error is present in independent variables, bias and inconsistency are highly likely to occur in the coefficient estimation procedure (Maddala 2001). Hence, a research model using this type of estimation method for pre-managed earnings is not appropriate. Therefore, following Phillips et al. (2003) and Roychowdhury (2006) we used post-managed earnings as the criterion to classify those companies with net profits slightly over zero as upward earnings management companies in this study.

boundary of bonus incentives. However, Gaver et al. (1995), which reexamined Healy (1985), found that accruals are adjusted such that earnings are increased. Thus, we decided not to predict the direction of earnings management in EM3, where the earnings are much less than zero. This implies that in this group, future corporate performance is unclear. Specifically, we defined companies with an ambiguous direction of earnings management as those where the value of NI divided by the total assets at the beginning of the current period was less than -0.075. TABLE 1 shows the numbers of company-years assigned to each bracket are 2,952 (EM1 1,337; EM2 1,205; EM3 410).[26]

****
Insert TABLE 1 about here
****

4.3 Empirical model

We used model (8) to test hypothesis 1. The dependent variable of equation (8), which represents REM (aggregate metric of the three real earnings management categories), takes into account ACFO (abnormal cash flow from operations), APC (abnormal production costs), and ADE (abnormal discretionary expenses). In this case, dependent variables that represent the real earnings management of equation (8) are the residuals that cannot be explained by the estimation model of equations (1)-(3) and the sum of the three residuals like equation (4)-(7).

A main explanatory variable is OWNH in these equations. OWNH is set to 1 if the proportion of majority shareholders' ownership exceeds the median value in each year, 0 otherwise. That is, OWNH represents relatively a higher majority shareholders ownership.

$$Y_t = \alpha_0 + \beta_1 \cdot OWNH_t + \beta_2 \cdot SIZE_{t-1} + \beta_3 \cdot MTB_{t-1} + \beta_4 \cdot NI_t + \varepsilon_t \qquad (8)$$

---

[26] We used different definitions (for example, 0.01 for EM1 or 0.065 for EM2 or -0.065 for EM3) of each incentive bracket for robustness check. The empirical results, however, are qualitatively the same.

$$Y_t = \alpha_0 + \beta_1 \cdot EM1_t + \beta_2 \cdot (EM1 \times OWNH)_t + \beta_3 \cdot EM2_t +$$
$$\beta_4 \cdot (EM2 \times OWNH)_t + \beta_5 \cdot EM3_t + \beta_6 \cdot (EM3 \times OWNH)_t + \qquad (9)$$
$$\beta_7 \cdot SIZE_{t-1} + \beta_8 \cdot MTB_{t-1} + \beta_9 \cdot NI_t + \varepsilon_t$$

where Y= REM, ACFO, APC, and ADE;
  REM= ACFO+ ADE+ APC;
  $ACFO$= (-1)×Residual from the estimation model of equation (1);
  APC= Residual from the estimation model of equation (2);
  ADE= (-1)×Residual from the estimation model of equation (3);
  $EM1$ = 1 in companies with NI slightly greater than 0 (0≤NI≤0.015), 0 otherwise;
  $EM2$ = 1 in companies with NI much greater than 0 (0.075≤NI), 0 otherwise;
  $EM3$ = 1 in companies with NI much less than 0 (NI≤-0.075), 0 otherwise;
  $OWNH$= 1 if the proportion of majority shareholders' ownership is higher than median value in each year, 0 otherwise;
  $SIZE$= Natural log of total assets;
  MTB= Market value of equity / book value of equity; and
  NI= Net income / beginning total assets.

In hypothesis 2, to compare and analyze the earnings management behavior of companies under different earnings management incentives brackets, we used equation (9). The dependent variables in estimation model (9) are identical to those in equation (8) used to test hypothesis 1. The independent variables of interest are EM1, EM2, EM3, an interaction term between each variable and OWNH, a dummy variable that indicates whether the majority shareholders' ownership is high. EM1 was used to test hypothesis 2a with a sample of companies with earnings slightly greater than zero, EM2 to test hypothesis 2b with a sample of companies with earnings much greater than zero, and EM3 to test hypothesis 2c with a sample of companies with earnings much less than zero. The dummy variable, OWNH, takes a value of one if the majority shareholders' ownership is higher than the median, and a value of zero otherwise.

****
Insert TABLE 2 about here

****

The expected signs of each variable of interest are summarized in TABLE 2. First, the companies with high majority shareholders' ownership tend to decrease real earnings management. OWNH, the variable of interest in hypothesis 1, is therefore expected to show significantly negative values. Second, the EM1 bracket containing companies with earnings slightly greater than zero is suspected to contain companies with upward earnings management. However, real earnings management incurs the sacrifice of the future value of the company, i.e., business myopia. Thus, while companies with low majority shareholders' ownership will perform upward real earnings management, those with a high proportion of majority shareholders will significantly control upward earnings management. As a result, companies with a low proportion of majority shareholders will have high Y (REM, ACFO, APC, and ADE), while those with high majority shareholders' ownership will have a smaller Y, according to the convergence-of-interests hypothesis. In a regression equation, the EM1 variable was positively correlated with Y, but the EM1×OWNH variable was significantly negatively correlated.

Third, the EM2 bracket containing companies with earnings much greater than zero is expected to practice downward earnings management. Their future corporate performance is expected to improve due to downward real earnings management, and it is therefore unlikely that majority shareholder monitor managers' myopic real earnings management. As a result, real earnings management will be done in such a way as to decrease earnings, regardless of whether majority shareholders' ownership is high or low. Thus, the EM2 variable is expected to show a negative correlation with the dependent variable and EM2×OWNH is predicted to be insignificant. That means real earnings management is not expected to differ depending on the level of ownership.

216

In the EM3 bracket containing companies with earnings much less than zero, however, it is difficult to predict the direction of real earnings management beforehand, regardless of the proportion of majority shareholders' ownership, because the impacts of upward earnings management for decreasing deficits and downward earnings management for the big bath both apply. Thus, it is expected that both the EM3 and EM3×OWNH variables will not have significant relationships with proxies for real earnings management (i.e., REM, ACFO, APC, and ADE).

As control variables, we first added the natural log of assets (SIZE) at the beginning of the period, considering that firm size has an impact on earnings management according to the political cost hypothesis, which states that a company tries to reduce earnings as it becomes bigger (Jones, 1991). Second, we included the market-to-book ratio (MTB), which accounts for growth opportunities in the market. We expect that as a company has more opportunities for growth, there is a downward earnings management incentive (Roychowdhury, 2006). Third, Dechow et al. (1995) and Guay et al. (1996) pointed out that earnings management incentive is related to firm performance. Hence, net income (NI) was included to control for firm performance.

4.4 Data Collection

The sample was selected from companies listed on the Korea Stock Exchange as of December 31, 2007 that satisfied the following criteria: (1) companies (except financial companies) listed on the Korea Stock Exchange, with their accounts closing in December; (2) companies with financial statements available for extraction using the KIS-Value of Korea Investors Services; (3) companies with information available about majority shareholder ownership using TS2000 of the Korea Listed Companies Association.

We used 17 years of data (1991 to 2007) from 7,358 companies that satisfied the above conditions. Samples were classified into 13 groups according to industry (SIC code)

217

to estimate real earnings management. To eliminate bias, 918 samples that were in an industry-year group with less than 30 samples were excluded from the sample pool. Furthermore, to eliminate the effect of outlier bias, the top and bottom 1% of independent and dependent variables were winsorized. A total of 6,440 firm-year samples were used for the analyses.

TABLE 3 shows the majority shareholder ownership of the companies. The majority shareholders' ownership of all companies was about 30%. It was about 17% in the lower-level group, and 43% in the higher-level group. When we compared the majority shareholders' ownership of companies according to earnings management brackets (EM1, EM2, and EM3), we found that it was almost the same for EM1 and EM3 but relatively larger in EM2.

****
Insert TABLE 3 about here
****

V. EMPIRICAL RESULTS

5.1 Descriptive statistics

The descriptive statistics of the variables used in the analyses are presented in TABLE 4. We compared the lower ownership group with the higher ownership group for all samples and for each earnings management bracket (EM1, EM2, and EM3).

First, we compared the difference between earnings management brackets. Abnormal cash flow from operations (ACFO), abnormal production costs (APC), and abnormal discretionary expenses (ADE) were relatively small in EM1 and EM3, but large in EM2 compared to the full sample. This difference implies upward earnings management in EM1 and EM3, and downward earnings management in EM2.

Second, we compared all the variables between higher and lower majority shareholder ownership groups in each earnings management bracket. In the whole sample and the EM1 bracket, the REM of high majority shareholder ownership was lower. However, in the EM2 and EM3 brackets, there was no difference between high and low majority shareholder ownership. The results with ACFO, APC and ADE were almost identical to those obtained using REM.

<div align="center">

****

Insert TABLE 4 about here

****

</div>

TABLE 5 shows the correlations between variables. OWNH had significantly negative relationships with REM and ACFO while it had negative but insignificant relationships with APC and ADE. This result is consistent with the idea that when the majority shareholders' ownership is higher, a company generally reduces real earnings management. Next, we use multivariate analyses to examine the effect of majority shareholder ownership on real earnings management according to earnings management incentive brackets.

<div align="center">

****

Insert TABLE 5 about here

****

</div>

5.2 Multivariate results

5.2.1 Test of hypothesis 1

TABLE 6 shows whether majority shareholder ownership is associated with real earnings management. A negative (positive) OWNH coefficient implies that a company avoids (conduct) real earnings management when majority shareholder ownership level is high. The result shows that OWNH was significantly negatively associated only with ACFO (at the one percent level). However, we were not able to find evidence of monitoring by majority shareholder ownership with REM, APC, and ADE. These results generally

219

suggest that there is no systematic relationship between the ownership and real earnings management.

<div align="center">

****

Insert TABLE 6 about here

****

</div>

SIZE, MTB, and NI were significantly negative in all models, which is consistent with the expectations discussed earlier.

5.2.2 Test of Hypothesis 2

When we tested hypothesis 1, we found no systematic relationship between the majority shareholders' ownership and real earnings management. However, majority shareholders have differential incentives in monitoring real earnings management if their sensitivity to real earnings management related to future performance is different as the prospect theory assumed. That is, monitoring by majority shareholders may only be effective in the upward earnings management bracket since it causes low operating performance in the future unlike downward real earnings management. Thus, to test hypothesis 2, we investigated the effects of the majority shareholders' ownership on real earnings management according to earnings management incentives. TABLE 7 shows the results of the test of hypothesis 2, and confirms that the results can differ according to their incentives.

<div align="center">

****

Insert TABLE 7 about here

****

</div>

Hypothesis 2a refers to EM1, which includes companies with upward earnings management incentive. All the coefficients of EM1 were significantly positive, and EM1×OWNH was significantly negative correlated with REM. This result was consistent across the ACFO, APC, and ADE models. Positive sign of EM1 indicates that these

<div align="center">220</div>

companies practice upward real earnings management to avoid deficits. In addition, negative sign of EM1×OWNH suggests self-control of real earnings management when the majority shareholders' ownership is high. In other words, majority shareholders resist making a decision that will decrease the company's long-term value. This result supports the convergence-of-interests hypothesis i.e. the interests of the majority shareholders and those of the minority shareholders are convergent (Jensen and Meckling, 1976; Klassen, 1997).

Hypothesis 2b refers to EM2, which includes companies with downward earnings management incentive. All the coefficients of EM2 were significantly negative, but none of the EM2×OWNH variables was significantly correlated with REM. This implies that downward real earnings management occurs regardless of whether the majority shareholders' ownership is high or not. We interpret this result as evidence that majority shareholders do not feel the need to block downward real earnings management because it does not damage long-term operating performance. When compared to upward real earnings management, this result is congruent with the prospect theory illustrating that investors including majority shareholders are more interested in evading loss than in pursuing profit.

Hypothesis 2c refers to EM3, which contains companies without obvious earnings management incentive. The signs of EM3 in TABLE 7 are not consistent across models, and most of them are not significant. Furthermore, none of the EM3×OWNH variables was significant. This result indicates that companies with large losses do not conduct real earnings management consistently, and the monitoring for real earnings management of majority shareholders is not apparent regardless of their ownership level.

The control variable results are similar to those obtained when testing hypothesis 1; negative signs in all models. That is, real earnings management decreases when firms are larger, growth opportunities are greater, and operating performance is better.

5.3 Additional analysis

The aim of this study was to examine the effect of majority shareholder ownership on real earnings management. We classified the types of earnings management into separate brackets and determined that upward earnings management incentives shrink when majority shareholder ownership was high. This result suggests that the higher the proportion of majority shareholders the more they are interested in a firm's long-term performance.

Furthermore, we performed an additional analysis to assess the impact of the proportion of majority shareholders on a long-term performance using the accumulated ROA from year 1 to year 5, as shown in TABLE 8. Since real earnings management has an impact on long-term performance, we expect to see a discrepancy in firm's performance between high and low majority shareholder ownership groups.

****
Insert TABLE 8 about here
****

TABLE 8 shows the differential impact on the firm's future performance in each earnings management bracket according to majority shareholder ownership. First, EM1 is significantly negative across all years (i.e., year 1 through 5), indicating that earnings management for loss aversion results in negative future ROA. On the other hand, EM1×OWNH is significantly positive from the year 3 through year 5. This result implies that a higher ownership of majority shareholders plays a significant role in monitoring

222

management not to impair long term operating performance although upward earnings management incentives present. Second, in the bracket of EM2 reflecting downward real earnings management, EM2 are significantly positive while EM2×OWNH are not significant in all period. This result suggests majority shareholders with higher ownership are not interested in as much downward as upward real earnings management. This may be because downward real earnings management in fact improves future operating performance. Third, EM3 are significantly negative and EM3×OWNH are significantly positive across all time periods. This result also suggests that majority shareholders with higher ownership keep management from acting detrimental to future performance. The results together imply that majority shareholders with higher ownership effectively control their managers not to implement myopic management decision that is harmful to future performance, confirming the hypothesis of convergence-of-interests between majority and minority shareholders. In particular, majority shareholders' asymmetric role across different earnings management incentive brackets may come from their loss aversion and is consistent with the prospect theory.

VI. CONCLUSIONS AND LIMITATIONS

To examine the convergence-of-interests or the expropriation-of-minority-shareholder hypotheses, this study adopted real earnings management instead of prior studies' accruals-based earnings management. Although majority shareholders allow accruals-based earnings management even with greater ownership, they may be more careful to real earnings management. It is because real earnings management has more direct influence on firm's actual operating performance. Thus, conclusions just with accruals-based earnings management may be so weak that we utilize real earnings management to test this controversial issue.

Moreover, based on prospect theory, we analyzed the differential effect of majority shareholder ownership on real earnings management according to earnings management incentives brackets. Prospect theory argued that investors are more interested in avoiding loss than pursuing profit. Consistent with the theory, majority shareholders are expected to be more reluctant to upward real earnings management.

We first found that, in the whole sample, there was no difference in real earnings management across different levels of majority shareholder ownership. Second, only in the bracket where earnings are suspected to be upwardly managed, real earnings management varied depending on equity ownership by majority shareholders. While companies with low majority shareholder ownership practice upward real earnings management to meet earnings benchmarks, majority shareholders with high levels of ownership prevent their companies from real earnings management. On the other hand, there was no difference in earnings management in the downward and ambiguous earnings management brackets across different levels of majority shareholder ownership. Third, we analyzed whether future performance with higher majority shareholder ownership is better or not. We found that cumulative performance (CAROA) in 3, 4, and 5 years is greater with high majority shareholder ownership in upward earnings management incentive bracket.

The results of this study suggest that the higher the proportion of majority shareholders is, the more they avoid upward real earnings management that may damage not only firm's operating performance but also their own wealth. This implies that majority shareholders tend to make less myopic decisions as they have more shares in their companies, which supports the convergence-of-interests hypothesis, i.e. the interests of the majority shareholders are aligned with those of the minority shareholders. Our finding is also consistent with the prospect theory in that the behavior of majority shareholders

224

with high levels of ownership is asymmetric between loss and profit. They are more interested in monitoring managers' upward real earnings management causing loss than downward real earnings management related to profit.

Our study defined earnings management incentive bracket only based on earnings level. However, it is known that managers have incentives to manage earnings under various corporate events such as seasoned equity offerings, executive turnover, newly introduced accounting regulation, and so on. If future studies investigate the effect of majority shareholders on real earnings management in these various incentives, their role to reduce agency cost will be better clarified.

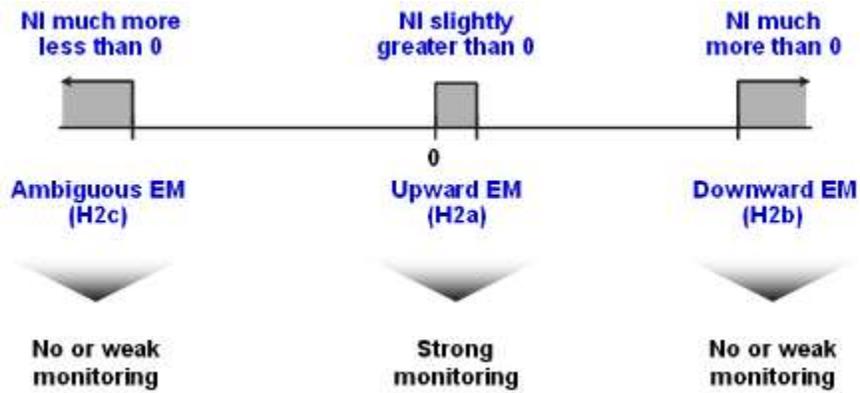
FIGURE 1
Classification of Brackets for Hypothesis 2


FIGURE 2
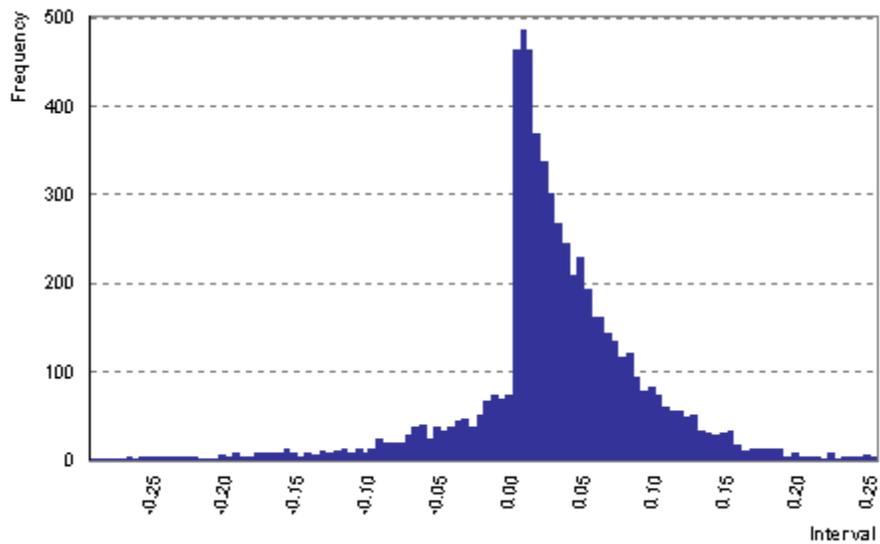
Distribution of Net Income


TABLE 1
Brackets of Earnings Management Incentives

Bracket		No. of companies
$EM1$	$0 \leq NI \leq 0.015$	1,337
$EM2$	$0.075 \leq NI$	1,205
$EM3$	$NI \leq -0.075$	410

Notes:

$EM1 =$ Companies with NI slightly greater than 0;

$EM2 =$ Companies with NI much more than 0;

$EM3 =$ Companies with NI much less than 0; and

$NI =$ Net income / beginning total assets.

TABLE 2
Predicted Signs of Variables of Interest

Hypothesis	Direction of EM	Variables	*REM*	*ACFO*	*APC*	*ADE*
1	N/A	*OWNH*	−	−	−	−
2a (NI>0)	(+) Upward Incentive	*EM1*	+	+	+	+
		EM1×OWNH	−	−	−	−
2b (NI>>0)	(−) Downward incentive	*EM2*	−	−	−	−
		EM2×OWNH	− /?	− /?	− /?	− /?
2c (NI<<0)	(?) Ambiguous Incentive	*EM3*	?	?	?	?
		EM3×OWNH	− /?	− /?	− /?	− /?

Notes:

*EM*1 = Companies with *NI* slightly greater than 0;

*EM*2 = Companies with *NI* much more than 0;

*EM*3 = Companies with *NI* much less than 0;

NI = Net income / beginning total assets;

OWNH = 1 if the proportion of majority shareholders' ownership exceeds median value in each year, 0 otherwise;

REM = *ACFO* + *APC* + *ADE*;

ACFO = Abnormal cash flow from operations;

APC = Abnormal production costs; and

ADE = Abnormal discretionary expenses.

TABLE 3
Majority Shareholders Ownership (%) in Each Bracket

Classification		Full sample		Low ownership by majority shareholders (OWNL)		High ownership by majority shareholders (OWNH)	
		Mean	Median	Mean	Median	Mean	Median
Total		30.0	28.7	16.9	17.5	43.1	40.9
*EM*1	0≤NI≤0.015	26.2	24.2	15.6	15.7	40.8	37.3
*EM*2	0.075≤NI	33.8	33.0	17.9	18.8	45.4	43.7
*EM*3	NI≤-0.075	24.1	20.9	14.5	14.3	42.6	40.0

Notes:

OWNH = Companies where majority shareholders hold more than the median value.

OWNL = Companies where majority shareholders hold less than the median value.

*EM*1 = Companies with NI slightly greater than 0;

*EM*2 = Companies with NI much more than 0;

*EM*3 = Companies with NI much less than 0; and

NI = Net income / beginning total assets.

RELATED PARTIES' TRANSACTION AND EARNINGS MANAGEMENT: A CASE IN INDONESIA

S u m i y a n a, *Universitas Gadjah Mada, Indonesia*
Rahmat Febrianto, *Universitas Andalas, Indonesia*

Abstract

This study investigates the association between related parties' transactions and earnings management in Indonesia. Firm's executives officers accompanied by board of director members usually engage in related parties' transactions to expropriate the firm's resources. Therefore, they have incentives to manage earnings either to increase their perquisites or possibly to mask such expropriation.

This study presents evidence that earnings management measures are positively associated with certain types of related parties' transactions. Overall, this study concludes that concerns about related parties' transactions as a factor associated with earnings management are warranted, especially for certain related parties' transactions. There are purchase costs from subsidiary or parent companies and expenses incurred from the firm's related parties' transactions.

Keywords: *related parties' transactions, perquisite, earnings management*

JEL Classification: M-42

BACKGROUND

This research is aimed to investigate the association between related parties' transaction and earnings management in Indonesia. Like the association between this transaction type and earnings management in the United States of America (Gordon and Henry, 2005), this association could be also evidenced in Indonesia. The company ownership structures in Indonesia are highly concentrated to one group, especially founding family (Claessens et al., 2002). It is used to fortify the interest of their own family founder (Shleifer and Vishny, 1997). The existences of this transaction were also supported by weak law enforcement and bad corporate governance that make the monitoring function becoming hard to be applied (La Porta et al., 1999).

The public companies in Indonesia were initially private companies founded by one family. The decision to seek fund from capital market was not fully followed by thorough issuance of company shares, nor even the control over the company. Most of the issued company shares will actually come to the family founder back. One way of such control is establishing some subsidiary companies (if they are not yet exist before) and then sells most of the company shares to its subsidiary companies. Besides, to maintain the control over the company, the family of company founder holds the position within company management. Claessens et al. (2002) investigated and discussed about this.

Issuing their shares bought by either family founder or subsidiary companies and establishing new subsidiary companies did not occur by itself. Gray (1988) argued that high tendency of collectivism, wide power distance, and high secrecy is common in East Asian companies, including Indonesia (Sudarwan and Fogarty, 1996). The argument above implies that many companies in Indonesia tend not to disclose too transparently about themselves, including their related parties' transaction.

The existence of related parties' transaction is not something prohibited. On the contrary, Indonesia Accounting Standard Boards (IASB) considers the related parties' transaction as normal transaction. However, IASB recognizes that related parties' transaction may have influence to the firms' financial position and income statements. The related parties may conduct transaction that cannot be done by ordinary related parties. This transaction can be done at the different price from similar transaction done by ordinary related transaction (Indonesia-SFAS No. 7, par. 6-7).

IASB attention to related parties' transaction in the matter of financial reporting in Indonesia is very relevant. Special-related parties' transaction is highly probable and even may dominate the most of all firms' transactions. Through specially parties' transaction, company earnings can be really manipulated, so it looks better than actually, while the cash and earnings can be distributed among the companies within the group. This transaction is not only occurred in the companies at developing countries, but it is also occurred at advanced countries (Jian and Wong, 2003). Actually, several companies at developed countries also use the related parties' transaction to transfer their assets and earnings for the majority shareholders.

There are many examples in Indonesia that can serve as evidence. The example is Salim family company network, the main owner of public company PT. Indofood Sukses Makmur (ISM). ISM has wide network and even to the upstream, i.e. PT. Bogasari Flour Mills, the raw material main supplier of instant noodle ISM product. ISM also has connection to the funding resource, namely Bank Central Asia. Besides ISM, there are still many more, if not said almost all of them, other companies in Indonesia also have special relation with one or more companies and do their various transaction types. However, as cited by IASB, the problems do not lay on the existence of special relation or on the transactions occurred among these parties. The problems arise when the executive officers

or board of director members take the chance for their own interest from the company's special relation.

A lot of parties, such as regulators and market participants, consider the related parties' transaction as a potential conflict of interest. Having the authority upon various inter-company transactions, the managers have powerful incentives to deceive the shareholders control rights and to overcome the monitoring function of shareholders and board of directors. The deceitful managers may use this transaction to gain more benefits of their positions or use it to justify (or even to increase) perquisites that they would gain.

The theory expresses that there are at least two alternative perspectives about related parties' transaction, which each has different implication to the earnings management. The first perspective is that related parties' transaction raises the agency issue, similar to the perspective by Jensen and Meckling (1976). According to this theory, the chief executive has incentive to manage earnings in order to justify their perquisites or even to secrete their company resources overspent. The second perspective states that related parties' transaction is merely rational company requirement to fulfill its economic objectives. By having special relation with other companies, a company binds itself with other parties to fulfill their economic requirement. For instance, by having special relation with other companies, a company may acquire knowledge and skills. In this case, the managers do not have incentive to manage earnings because there is nothing to omit or eliminate. As a bonding mechanism, the special relation binds the related parties. The tendency to take risky actions such as earnings management will only endanger the company or its related parties (Gordon and Henry, 2005).

Both the first and second perspectives are interesting when used to investigate whether the related transaction in Indonesia is used in order to manage earnings or just to fulfill rational economic requirement. Companies' managers with concentrated ownership structure have two contradictive possibilities of their behavior. First, according

to alignment effect hypothesis, the managers of a company with concentrated ownership structure do not deceive and injure the minority shareholders. As a part of the company family owner, they are expected to report all transaction fairly. However, the second, entrenchment effect hypothesis expects otherwise. Because the law enforcement which does not support the property right well, the managers try to protect their own interest, which is to represent the control rights of company family founder or the majority shareholders (Shleifer and Vishny, 1997). Therefore, to protect themselves, there is a tendency to report transaction unfairly (Fan and Wong, 2002, Jung and Kwon, 2002). They conclude that discussion and empirical evidences pertaining to these hypotheses including empirical evidences have derived from both alignment effect hypotheses and entrenchment effect hypothesis in East Asia. They suggest that for all of transaction types that are most possible to be omitted is the related parties' transaction.

To audit for financial statements having much related parties' transaction is not an easy matter. AICPA (2001) gave three reasons why the parties having special relation and transaction with the special relation is hard to be audited. First, those transactions are not always easily identified. Second, even though other procedures have been conducted properly, the auditor usually let the management and the company owner to disclose their special relation with the other company and also the transaction among them. Third, those transactions are not always easily identified by the company itself.

Interesting empirical question from the discussion above is, considering legal condition, highly concentrated structure of ownership, and the cultural effects against accounting practice, whether related parties' transaction is used by the company to manage earnings or not. If empirically proven that related parties' transaction is associated with earnings management, the second question is which transaction is used

to manage earnings, among all seven transactions that have to be disclosed according to Indonesia-SFAS No. 7.

The answers to these research questions give new perspective about how earnings management is conducted. Previous researches about earnings management, especially the ones using Jones model (Jones, 1991) or its modification (Dechow et al., 1995), have never differentiated the sales or transactions according to their nature: whether the transactions occurred among independent parties or not. The related parties cannot be considered as independent, even though legally they are different entities. Therefore, transactions among related parties can always be utilized for executive interest which in turn may injure the interest of outsider or minority shareholders. The evidence of earnings management pattern among related parties may serve as input for the regulators and standard makers to public regulation, especially related to the related parties' transaction disclosure.

THEORITICAL FRAMEWORK

Accounting and reporting regulation

There are two main sources of accounting and reporting regulation on related parties' transaction, namely Indonesia-SFAS No. 7 and Indonesia SECs' regulation. Indonesia-SFAS No. 7 directs guidance to disclose transaction with related parties. Special-related parties' transaction also directed by Indonesia SECs' Regulation No.: VIII. G.7, about Financial Reporting Presentation Guide.

Indonesia-SFAS No. 7 states that parties who have special relation with the company are as follow, (1) company that control or being controlled or under common control with the company report publisher; (2) associated company; (3) company that has the right to vote at company report publisher and close family member of these individuals;

(4) company key employee; and (5) company where the substantial interest in the right to vote is owned either directly or indirectly by each person described at point (3) or (4), or each person above has significant influence over the company.

Paragraph 17 regulates some examples of transaction that need to be disclosed which generally are all transactions that potentially influence the company performance, from sales and purchases of goods and services, transfer of assets, financing, and contracts. Paragraph 19 explains that each transaction has to be disclosed in transaction volume, number or proportion of intermediary items, and pricing policy.

Appendix No.: Kep-06/PM/2000 of Indonesia SECs' Regulation No.: VIII. G.7 regulates to disclose all companies' transaction with related parties. This regulation describes in detail that these transactions have to be disclosed, namely:

1. Detailed number of each account of assets, liabilities, sales and purchases (expense) to the related parties along with the percentage against total assets, liabilities, and sales and purchases (expense);

2. If the sum of each transaction or the balance of each category with certain party is greater than Rp1.000.000.000,00 (one billion rupiahs), the sum must be presented separately, the name and related party must be disclosed;

3. The explanation of transactions which are not related to the main operation and the sum of payable/receivable related to those transactions;

4. The nature of relation, types and elements of related transaction;

5. Pricing policy and transaction condition along with the statement of whether the application of pricing and condition policy are equal with the pricing and condition policy for transaction with third party; and

6. The reasons for the basic establishment of related receivable allowance.

In other side, both Indonesia-SFAS and Indonesia SECs' regulations also add a statement, "… notes on financial report must present separately the sum of each transaction and balance with the directors, employees, boards of directors, major shareholders, and parties which have special relation …" They actually show clearly that, even though the related transaction is normal activities during company operation, this transaction gives incentive to the manager to act deceitful for their own interests and disregard the shareholders interest. In the case of Indonesia, the minority shareholders who are not part of the family of company founder would be losses their welfares.

Earnings management literature

Earnings management occurs when the company managers use their discretionary accounting accrual in presenting financial statements and transactions controls. They do to deceive the outsider users about their base economic performance or to influence contractual output which depends on reported income numbers (Healy and Wahlen, 1999). Previous studies have tried to investigate the incentive and the mechanism of earnings management. However, most studies focused on earning management through financial reporting, especially discretionary accounting accrual. Jones (1991) developed a model using the change of incomes and property, plant, and equipments to estimate the nondiscretionary accrual. He found that the companies in industry which request the unlocked import faucet tend to decrease their discretionary accounting accrual during two or three years before.

Healy and Wahlen (1999) concluded that earnings management literature can only give modest input to the standard makers. According to them, the motivations of earnings management come from: (i) expectation and judgment of capital market, (ii) contracts they wrote in form of accounting income numbers, and (iii) anti-trust regulation or other government regulation. Their finding indicates that earnings management occurs for various

reasons. Those are to influence the capital market perception, to increase management competency, to decrease infringement tendency of debt-contract covenant, and to avoid regulatory intervention.

In the matter of related parties' transaction, empirical research theory implies two alternatives of perspective. The first perspective states that related parties' transaction causes agency issue, as presented by Jensen and Meckling (1976). Jensen and Meckling categorized agency conflict between managers and outsiders shareholders as the managers' tendency to spend company resources for their personal interests, similar to perquisites. Accounting and business articles and accounting standards believe that related parties' transaction shows potential of company resources spending for personal interest, namely expropriation (Gordon and Henry, 2005).

If the company chief executives and/or the boards of director members will involve in related parties' transaction, their personal interest expenditure (perquisites), they would have incentive to manage earnings in order to justify (or to increase) their personal financing or to omit their personal expenditure. This perspective is consistent with the definition by Schipper (1989) about earnings management as an intentional intervention to the financial reporting process, in order to gain personal benefits.

Another perspective considers the related parties' transaction as another form of economic demand or a mechanism that binds one or more parties involved in the company (Gordon and Henry, 2005). For example, an associated company that is generally known to have considerable service knowledge is greatly required by another company. Therefore, it is more effective for the company to cooperate with its associated company rather than the other outsiders. In this case, it is reasonable that there is no incentive for the manager to manage earnings because such cooperation does not need to be covered up. Therefore, this relationship formulation does not give expected benefits for those companies from

existence of the association between the earnings management and related parties' transaction.

The same logic is also applicable to explain someone's motivation having special relationship with the company. For example, the company employed the sons of chief executive officers or board of director members. Because of their occupancies, chief executive officers and his son depend on the company where they work, and then the chief executive will not take action that may endanger the company, such as earnings management that may ruin the company or his son's relationship with the company. Another example, a board of director has a contract as a consultant company. If the board of director had tendency to manage earnings, his position within the board of director or his agency contract may be terminated. Therefore, as a bonding mechanism, transaction with related parties devotes a very limited or small incentive to drive earnings management.

Contradictive points of views about related parties' transaction show the complexity matters. The assumption hold by the standard makers is that such transaction is not conducted independently, unlike transaction between non-affiliated parties. A part of such transaction may be based on different recognition and measurement rather than regular transaction (US-SFAS No. 57, par. 3 and Indonesia-SFAS No. 7, par. 7). Accounting standards regulate to disclose these related parties transactions because the information contents of such transactions may be useful for the all of financial statement users to accounting information comparability (US-SFAS No. 57, par. 18 and Indonesia-SFAS No. 7, par. 18-19).

Related to the concern that such transactions were not conducted independently and fairly, many companies disclose that their contracts were made with related parties under conditions that were at least equivalent to any other parties. If a company conducted a transaction with certain parties having special relationship or at least could increase and did not reduce stock holders welfare, there would not be any negative impact for the

company and there would not be any reason to manage earnings. However, according to Henry and Gordon (2005), due to the cost other than contracting cost, the disclosure of related parties' transaction does not always mean that the company is not affected by this transaction. There are some other economics costs for the company who conducted transaction with related parties, such as monitoring cost, opportunity cost, and reporting complexity cost.

Some research has been conducted to obtain deep understanding about this transaction. Gordon and Henry (2005), for instance, studied the relationship between this transaction and earnings management. They found evidences that adjusted absolute abnormal accrual are related to certain special party and to certain transaction type. They showed that transactions involving fixed rate interest financing with firms' related parties, either its existence or its sum of dollar, is associated positively with adjusted absolute abnormal accrual which serves as earnings management indicator.

Gordon et al. (2004) found that transaction with related parties usually associates with the corporate governance mechanism. It usually is marked with low management compensation and low market return. Kohlbeck and Mayhew (2004) found that some related parties' transactions associate with the chief executive compensation, while the others do not. Cheung et al. (2004) who studied in Hong Kong stock exchange finds that companies whose ownership characteristics is highly concentrated and institutional ownerships. The specific market characteristics in Hong Kong stock exchange have implied that traders of the concentrated shareholder ownership or institutional ownership are able to do stock trading with inter parties having special relationship. They find that positive abnormal return during the announcement of such transactions is associated with the ownership percentage of stockholder control rights and serves as a proxy of information disclosure. Jian and Wong (2003) proved that the debt-covenant companies report their sales level with the related parties' items higher than non debt-covenant companies. They

had incentives to inflate their accounting earnings to avoid eviction from the stock market or before they issued new shares.

Studies related to board of director composition using the existence of related parties' transaction are aimed to classify the member of non chief executive directors as affiliated or grey directors (Klein, 2002a, Vicknair et al., 1993, Hermalin and Weisbach, 1988). Affiliated board of director is considered as non independent member. Klein (2002b) examined the association between earnings management and audit committee independence and board of directors' independence. Based on the role of audit committee as the mediator who reduce conflict between management and auditor, they were expected to produce more accurate audit reports. Klien (2002b) hypothesized that an independent member of audit committee is the one who could play his role as an active supervisor against financial reporting process. He predicted that audit committee independence is associated negatively with earnings management. He later found that the audit committee independence and director independence are associated negatively with earnings management. In addition, he concludes that independent directors could monitor effectively firms' financial reporting process.

Hypotheses Development

The transaction between a company and its related parties can be seen from two perspectives; opportunistic and normal operational. Indonesia-SFAS No. 7 par. 16, for instance, states that the company transactions with its related parties are not always based on opportunistic motives. Special related parties' transaction might be possible because it must be done for the company survival. Furthermore, the affiliated company is the only one product buyers. However, unrelated to such matter, the manager's incentive to do opportunistic transaction with affiliated company is highly supported by

the law enforcement. Within strong law enforcement, including the transparency reporting regulation, the incentive to deceit earnings management is less than within weak law enforcement.

The law enforcement in Indonesia is not yet strong, if not said otherwise. Within such enforcement, the way of company owner-founder to protect its property right is dominant ownership over the company at stock market (La Porta et al. 1999). Majority ownership is not the only way, so that they don't loose their control right over this company. To maintain their control right, the company must grow well. Company with good profitability has less probability to be overtaken by its competitors. Considering the ownership structure that is highly concentrated to one founding family because due to the weakness of property right regulation and managers as part of founding family. We may assume that company managers try not to loose their control rights. La Porta et al. (1999) suggests that the Indonesia companies before going initial public offering have previously set subsidiary companies to buy their issued shares. Most subsidiary companies usually have business line connected to parent companies. Thus, the incentive to do transaction with its related parties is clear enough. Similar to Klein (2002b), Gordon et al. (2004), and Gordon and Henry (2005), our maintained hypothesis is that related parties' transactions are associated with earnings management. Therefore, this study suspects that the related parties' transaction associated with earnings managements.

__H1__: Special-related parties' transaction items associated positively with earnings management.

RESEARCH MATHODS

Sampling

The sample consists of all manufacture companies whose shares are listed at Indonesia Stock Exchange (IDX), that include all shares listed at Jakarta Stock Exchange before its merging with Surabaya Stock Exchange). The focus on manufacture companies was aimed to ensure that the conclusion is not affected by other industry characteristics. The weakness of this sampling method lies on its generalization validity. However, in order to obtain stronger conclusion, the weakness has been minimized.

The companies included within sample should have complete financial data; those are cash flows, total assets, liabilities, sales, net income, and market value. Sample also should have adequate explanation about its related parties' transaction. Sample was selected from last ten years of reporting.

Operational Definition and Measurement

Independent variable

The disclosure about parties who has special relationship with a company within sample may be obtained from the company financial report. Indonesia-SFAS and Indonesia SEC regulations require some related parties' transaction disclosure at financial statements. Special-related parties' transaction may be categorized into four dimensions, namely transaction involving primary parties, transaction involving secondary parties (if any), types of related parties' transaction, and the sum of related parties' transaction. Parties are considered as primary by their relationship with the company. These primary parties include management, board of directors, majority shareholder (owner), subsidiary company, associated company, and affiliated company.

Secondary parties consist of various individuals, such as family member of primary parties, company owned by primary parties, company that has the same key management as primary parties, primary parties affiliated company or parties, and management of subsidiary company. If transaction occurred directly between one primary party and company (for example, the company gave loan to its associated company), there would be no secondary parties involved.

The third dimension is the type of transaction. Various types of transaction are identifiable within this research, including direct service delivery between related parties, goods or services purchase contracts with related parties, sales to related parties, loan, investment, and others. The last dimension is the rupiah sum of transaction conducted by the company with its related parties. Principal summing was calculated for loan, fixed-interest rate financing, investment, and other single transactions. Annual summing is used whether transaction continue or occur frequently in sequential years such as goods/services purchase contract and sales.

Dependent variable

This research uses abnormal accrual as earnings management measure. This measure has been widely used in earning management research. To calculate total accrual, this study starts from expected accrual estimation using modified Jones model (1991) as follows.

$$\text{ACCR}_{j,t}/\text{TA}_{j,t-1} = \alpha(1/\text{TA}_{j,t-1}) + \beta(\Delta\text{REV}_{j,t}/\text{TA}_{j,t-1}) + \chi(\text{PPE}_{j,t}/\text{TA}_{j,t-1}) + e_{jt} \tag{1}$$

where, ACCR$_{j,t}$ is total accrual for company j *during year* t*, which is net income subtracted by operating cash flow, TA$_{j,t-1}$ is total assets, ΔREV$_{j,t}$ is change of net sales, PPE$_{jk,t}$ is gross value of property, plant and equipment (fixed assets),* e *is residual*

errors. Abnormal accrual is calculated using estimate resulted from equation (1), and

then applied in the following equation (2).

$$AAC_{j,t} = ACCR_{j,t}/TA_{j,t-1} - [\alpha(1/TA_{j,t-1}) + \beta(\Delta REV_{j,t}/TA_{j,t-1}) + \chi(PPE_{j,t}/TA_{j,t-1})] \qquad (2)$$

where, $AAC_{j,t}$ is abnormal accrual for company j during year t. Abnormal accrual is used as independent variable to examine the association between related parties' transaction and earnings management.

Analysis method

Unlike the independence of audit committee or board of directors, company-specific scale for related parties' transaction is unclear. The logic measure of audit committee independence or board of director is the number of independent committee or directors divided by the sum of audit committee or board of director members. On the other hands, the absence of the sum of every transaction type and with which firms do relationships make company-specific scale of related parties' transaction identification to be difficult (Gordon and Henry, 2005). Therefore, this research examines various measures of related parties' transaction as independent variable, including number of company transaction types, whether the company has transaction with primary or secondary parties, or certain type of transaction, and sum of disclosed transaction, if available.

Later, this study calculates abnormal accrual for each measure of related parties' transaction. If earnings management did exist, positive and significant association between abnormal accrual and related parties' transaction is expected. This study constructs by adding other factors that have been known to have association with earnings management. This addition is important to prevent the mistake of null hypothesis rejection about the

absence of abnormal accrual when the null hypothesis is actually true (Bartov et al., 2000, and Klein, 2002b). Previous researches have found positive association between preceding year profitability with earning management. To capture expected growth, the researcher includes equity market value. Additionally, this research includes operating cash flow and one indicator for negative income to control other properties of accounting earnings and accrual. Previous researches have found that leverage associates positively with earnings management (DeFond and Jiambalvo, 1994). Finally, the researcher includes political cost measured by company value, because political cost has negative association with earnings management. This regression model is formulated in the following model (Gordon and Henry, 2005).

$$AAC_{jt} = \alpha + \beta RPT_{j,t} + \gamma_1 Abs(\Delta NI)_{j,t} + \gamma_2 MV/BVA_{j,t} + \gamma_3 OCF_{j,t} + \gamma_4 NegNI_{j,t-1}$$

$$+ \gamma_5 Debt_{j,t} + \gamma_6 Log(Assets)_{j,t} + e_{j,t} \tag{3}$$

where, AAC_{jt} is abnormal accrual for company j during year t, RPT is the measure of related parties' transaction, Abs(ΔNI) is absolute value of net income change divided by one year of total assets lag, MV/BVA equity market value divided by equity par value measured during the beginning of the year, OCF is cash flow during year t divided by total assets during the beginning of the year, NegNI is indicator variable which equals to one if the company reported negative earnings during preceding year and to zero if otherwise. Debt is long term liability divided by total assets at the beginning of year, and Log(Assets) is logarithm of total assets.

In order to examine further and to enhance the method used by Gordon and Henry (2005), this research re-investigates the previous regression examination result. This research examines by differentiating discretionary accounting accrual into positive

and negative discretionary accrual as dependent variable. This considers the sensitivity in which the measure of related parties' transaction affects discretionary accrual. More specifically, this examination suspects that the one affected is not at the base of accrual measure, but the probability of increase or decrease of accrual measure. The formulation of regression is as follows.

$$Ln(V_{AACjt}/(1- V_{AACjt}))= \alpha + \beta RPT_{j,t} + \gamma_1 Abs(\Delta NI)_{j,t} + \gamma_2 MV/BVA_{j,t} + \gamma_3 OCF_{j,t} +$$

$$\gamma_4 NegNI_{j,t-1} + \gamma_5 Debt_{j,t} + \gamma_6 Log(Assets)_{j,t} + e_{j,t} \qquad (4)$$

where, V_{AAC} is the probability of increase or decrease of abnormal accounting accrual for company j during year t, other explanations of all independent variables are the same as previously mentioned. The hypothesis that related parties' transaction associates with earnings management is when this RPT coefficient (β) variable from equation (3) and (4) have positive value and statistically significant.

RESULT ANALYSIS

Descriptive Statistics

The result of descriptive statistics examination is presented at Table 1. The mean of company sample that has income (in absolute value) is Rp140 billions, and the median equals to Rp30 billions. The operating cash flow has mean of Rp11 billions and median of Rp26 billions. Both mean and median values of operating cash flow show that sample curve tends more to the right side and the sample values lie more in the left side from normal

curve. Similar conclusion is applicable for liability, but not for total assets that has been deflated by natural logarithm.

Insert Table 1 about here

Table 2 presents the descriptive statistics of related parties' transaction form company sample. The mean of related parties' number own by a company equals to 8.18. A company, for example PT. Daya Sakti Unggul Corporation, reported the biggest number of related parties, which were 34 related parties during 1997. However, this number reduces to approximately nine percents during 2006. Using frequency distributions for each related party who did transaction with company sample shows highly rank. The highest frequency of related parties that have disclosed transaction equals to nine percent, which is at sixth grade special related parties. Eighty percent of observation sample reports the number of related parties under 12 parties.

Insert Table 2 about here

Special-related parties' transactions which have zero values do not mean that the company did not do transaction with its related parties every year. For example, the zero value of related parties account receivable does not mean that there are no account receivable transactions or other receivables. The zero value only shows that the company did not disclose the transaction at all or disclosed the transaction but hidden the item

number. Inversely, the company may not report the name of its related parties' items, but disclosed only its related parties' transaction. This research includes this transaction into analysis.

This research reviews that related parties and the transaction whose values presented at Table 2 is just as much as the financial reporting disclosure. Some companies clearly stated the item numbers, for example the employee and directors' receivables. Other companies only stated that such receivables did exist but did not disclose the item numbers of the receivables. Usually, they only showed that such receivables are combined with other assets into "other assets" classified-account. When this occurred, the researcher did not include into analysis.

Hypothesis Examination

Table 3 shows the result of bivariate inter-correlation examined variables. This relationship serves as initial evidence about the relationship among variables observed in this research. Abnormal accrual (AAC) has positive relationship with net income, dummy negative/positive income, and total assets. The relationship between income and abnormal accounting accrual that has positive sign shows that income associates with abnormal accrual. Inversely, operating cash flow associates negatively with abnormal accrual. This relationship is in accordance with the prediction of previous researches.

Insert Table 3 about here

Table 4 shows the regression result between all variables within this research. The researcher conducts two kinds of regression. First regression is aimed to proof the

existence of earnings management at company sample. Meanwhile, the second regression puts related parties' transaction variable into regression equation. There are six variables that are related to this transaction, namely sums of related parties who do transaction for all year long, receivables, incomes, debts, purchases, and expenses those occur due to company's transaction with its related parties. Each variable at the second examination is included into the regression model once only.

Insert Table 4 about here

All seven regressions show F-values those are statistically significant. Adjusted R^2 values are approximately 28%, except the seventh equation. This result shows that the variables are associated with earnings management. The biggest F-value is shown by equation reg-7 that equals to 37.150. This high value is caused by significance of related parties' transaction variable. The detailed result for each variable is as follows. Net income shows positive signs and significant associations as predicted. From all seven regressions, it is shown that absolute income variable is always statistically significant. In other words, absolute income affects the managerial action to manage accounting and reporting its earnings.

Operating cash flow has direction that is in accordance with predicted signs. Because accounting is based on accounting accrual, the usage of cash basis is able to prevent earnings management, or at least cash basis has negative association with this managerial behavior. Basically, earnings management usually associates with the company operational activities, so that operating cash flow is suspected to have negative association with earnings management. The examination results present negative association evidence

that is statistically significant for all equations. Negative income dummy variable values one if the company reported losses or zero if otherwise. Except for second and sixth equations, this variable does not show statistically significant results. It means that losses income numbers associates statistically significant with earnings management.

DeFond & Jiambalvo (1994) suggests that leverage associates positively with earnings management. This study used long term debts as a proxy of leverage. Our current study shows results that debts associate positively and statistically significant at three of four regression equations. However, at first equation, debts are unable to explain statistically about the behavior of earnings management.

Total assets as a function of political costs hypothesis do not have sign direction as predicted. The sample does not show that political costs are the consideration for the company to do earnings management. The behavior of company managers is not to lessen company assets when they manage their earnings. This phenomenon is completely different from political costs hypothesis which predicts that company tends to avoid it (Watts & Zimmerman, 1986).

From six variables of related parties, only the purchases variables between the company and its related parties and expenses of related parties' transaction that is statistically significant. The company sample does earnings management by increase its purchases with its related parties. Additionally, this examination shows transactions that make the company managers to put transaction expenses in its financial reports that positively affect earnings management. Both purchases and transaction expenses has relationship in the process to affect earnings management. The reason is, both purchases and transaction expenses are to be used as tools to lower company income. Greater purchases raise costs of good sold and then decrease their income. Similar process applies to transaction expenses. Therefore, the regression result is coherent with the conclusion of dummy variable above.

SENSITIVITY ANALYSIS

To re-examine the result of linear regression test, this research do similar variables using probabilistic regression which is based on the probability of positive and negative abnormal accrual. The detailed result is presented at Table 5 as follows.

Insert Table 5 about here

All seven probabilistic regressions show result of -2 log likelihood values which are statistically significant. Negelkerke-R^2 values are approximately 26%. This result implies that probabilistic regression examination strengthen the validity result that has been obtained from linear regression examination. The associations between various variables and earnings management are relatively equal which are explained in detail as follows. The change of absolute net income does not affect abnormal accrual during the equivalent years. Meanwhile, operating cash flow, negative income, debts, and total assets are always statistically significant and have signs those are in accordance with prediction. In other words, all variables except net income affect the action of company earnings management.

From six related parties' transaction variables, only purchases between the company and its related parties are statistically significant. This means that the companies sample do their earnings management by increasing the sum of purchases to its related parties. This only one, that is purchases, has association in its process to affect earnings management. Therefore, this study concludes that purchases are tool used to lower current accounting income. Greater purchases increase the cost of good sold and then lower accounting income.

FINDINGS AND DISCUSSION

This research finds that purchases have relationship with earnings management. This finding is highlighted that most Indonesia companies are subsidiary of other foreign companies. This relationship shows that most Indonesia companies have capital dependency to their parent companies abroad. Because of subsidiary company, it often does purchases from parent company, for instance, PT. Voksel Electric reported purchases raw material and spare parts from its affiliated company up to 81% from its total purchases during 2004. This fact indicates that Indonesia firms depend upon their parent company, especially on raw material imported for their products. However, not every company should depend on raw material from abroad. For example, PT. Barito Pacific Timber even sells its products to its parent company abroad. This research suspects that different business characteristics among Indonesia companies make purchases significance to be just at the level of 5%.

Another significant variable is expenses of related parties' transaction. This variable affects earnings management at significance level of 1%. Unlike the explanation about purchases from related parties above, expenses are relatively easier to use for parent or subsidiary company as earnings management instruments. This expenses charging can be used by the company to lower its earnings during a period and report earnings lower than it should be.

Both expenses and purchases provide incentives for managers to lower their company earnings. This result supports the finding of negative income dummy variable. It means that company sample tendency is to lower accounting income than otherwise. More specifically, companies tend to use purchases and expenses transaction as tool to lower their reported income. The usage of purchases and expenses transaction to lower reported income can be explained by observing the macro economics condition around research

observation period. Since 1995, Indonesia governmental regulation has required all companies who have more than Rp100 millions accounting income to aid Yayasan Sejahtera Mandiri. This policy obviously burdens the companies and serves as trigger for the companies to report lower income than it should be. Even though, this obligation has been abolished at 1998 or 1999, marked by its absence at financial reports, but then macro economic condition has worsen because of economic crisis. This crisis made most companies tend to report lower reported income even more. The recovery which is time consuming makes earnings management practice with predisposition to lower reported income occurs again.

CONCLUSION

From data observation, this research concludes that not all companies within sample report and own related parties transaction as stated Indonesia-SFAS No. 7. From 450 observations, as many as 5.6% observations have related parties which equal to zero. This research presents evidence that earnings management measures are positively associated with limited types of related parties' transactions. Overall, this study concludes that concerns about related parties' transactions as a factor associated with earnings management are warranted, especially for certain related parties' transactions. There are purchase costs from subsidiary or parent companies and expenses incurred from the firm's related parties' transactions.

However, this absence of related parties reported by companies in financial report has three possibilities of reasons. *First*, the companies do not really have related parties who do transaction with the companies during reporting year and there are not any transactions with related parties to be reported during the current year. *Second*, the companies actually have transactions with related parties but did not report which related parties, although the transactions and their sums were disclosed. This occurred when the

currency values of the transactions were considered relatively small so that they were included into account of "purchases to related parties", without explanation about which these related parties are. As previously mentioned, this research included zero value as the sum of related parties, even though in fact this research included transactions value according to their groups and their sums.

Third, companies actually have transactions with related parties but did not disclose them in their financial statements. This was found at the notes of financial statements which implied that those transactions occurred, such as the company dependence to raw material from associated company abroad. Such phenomenon was normal considering that related parties' disclosure and their transactions depend on chief executives and board of directors' desires. Companies such as Medco Energy [27], have tens subsidiary companies and disclose them in financial statements. Actually, the company only disclosed some of them. The financial statement users can only rely on the accounting information disclosed.

The full, fair or adequate disclosure of related parties and their transactions was affected by various factors, from management culture to disclosure costs. Additionally, related parties' transactions have operational and economic motives. Therefore, the expression that related parties' transactions were conducted under the same condition as third parties transactions, the related parties' transaction disclosure may be considered by the chief executives and board of directors or auditors as uneconomical and do not affect the firms' fundamental value. The majority control rights among companies which are very complicated makes the disclosure become expensive for the company.

The related parties' transaction disclosure becomes sensitive for the company when such transactions involved stockholders or company founders. Transactions that usually

---

[27] This research excluded this company from sample for changing its functional currency from Indonesian rupiah to US dollar during 2002. This change caused the variables measurement become hard, because some transaction used currency exchange rate at transaction date, such as sales. Meanwhile, some other transactions used historical currency exchange rate, such as fixed assets.

occur between company and stockholders are other payables-receivables. Only few number of companies within sample disclosed that the company conducted transactions with stockholders and the full disclosure of involved stockholders' names. Usually such transactions were disclosed under "receivables to stockholders" or "payables from stockholders" labels without full disclosure of involved stockholders' names.

The disclosure by company was not entirely adequate so it covers who and how much transaction between the company and its related parties had been recognized. Some companies only disclosed in narrative form which stated those related parties' transactions have occurred without detailed explanations about the sum of transactions. The presented figures are the only evidence of a certain figure. For example, some companies disclosed its purchases to related parties compared to total purchases. Some other companies even disclosed in rough percentage by adding "approximately." Besides the transaction disclosure which is unclear, there is no uniformity on the disclosure among companies. Some companies disclosed their transaction, such as account receivables to related parties under account receivables group. Meanwhile, some other companies separated their third parties from related parties. However, it is not uncommon that companies disclosed these transactions under sections other than transactions as found in this study. For example, costs occurred from agreement, such as royalty payment to principal, were disclosed under the group of "agreement or contracts and bonding."

Culture (Gray, 1988; Sudarwan & Fogarty, 1996) and weak law enforcement in Indonesia (La Porta et al., 1999) serve as explanation about evidence that the disclosure of Indonesia companies were bad and irregular. Most Indonesia companies were founded by family and they want to stay in their companies because they do not want to loose their ownership entirely. Secrecy is often considered as one way to maintain their control rights. When it was chosen, then the disclosure becomes weak and bad.

Company is the only side who understand certainly with whom the firm management does transactions. Not only have the users of financial report depended on full information disclosure from companies, but it also does the auditors. This study is only able to identify related parties as long as they were disclosed by the company. In this research, we find that company did transactions with other companies or subsidiary companies whose names those were so much alike, but they were still considered as third parties. However, they were reported as related parties a few years later. This shows that executive officers and board of directors are the only information sources and firm disclosures are the only ones which can be used by financial statement users.

Further research is recommended to improve the metric of related parties' transactions measurement. This research used the metric of research by Gordon and Henry (2005). The research acknowledged that this metric is not yet good enough to capture the phenomena of related parties' transactions. Some transactions were used overlapping in examinations, for examples, sales transactions. Jones' model (1991) uses sales to estimate accrual. The sales values itself were previously used to determine abnormal accrual. Our study concludes that the procedures of accrual estimation and its association with sales becomes bias to conclude.

1.4 Capital Markets

FURTHER EVIDENCE FROM EMERGING CAPITAL MARKETS THAT BOTH FIRM-SPECIFIC AND MARKET-WIDE REGIME SHIFTING BEHAVIOR APPROACH EXPLAINS ASYMMETRIC PRICE REACTION

Abstract

This study investigates if the market reacts asymmetrically to earnings shocks and if both firm-specific and market-wide regime shifting behavior approaches explain the asymmetric price reaction. Using data from three emerging stock markets—Indonesia, Kuala Lumpur, and Manila Stock Exchanges—for the period of 2002-2007, this study finds that stock prices react asymmetrically to earnings shocks. It also finds that both firm-specific and market-wide approach explains the asymmetric responses. These findings are consistent with those from well-developed capital markets.

Keywords: *earnings shocks, asymmetric reaction, firm-specific approach, market-wide regime shifting behavior approach*

1. Introduction

Earnings shocks—defined as the difference between actual earnings and expected earnings—have been posited to affect firms' stock prices in a positive direction. That is, positive (negative) earnings shocks will lead to a positive (negative) price reaction. The magnitude of the reaction, however, differs significantly. That is, the magnitude of reaction to positive earnings shocks is different from that to negative earnings shocks (Skinner & Sloan, 2002; Lopez & Rees, 2001; Conrad, Cornel & Landsman, 2002).

Two different approaches—firm-specific as well as market-wide regime shifting behavior—are commonly used to analyze the asymmetric reaction. Proponents of firm-specific approach argue that the asymmetric phenomena result from an inefficient stock pricing. Skinner & Sloan (2002), for instance, find that (i) growing stocks react more excessively to negative than to positive earnings shocks, and (ii) returns of growing stocks differ from those of blue chips ones. Lopez & Rees (2001) find that firms successfully achieving the analysts' prediction have earnings response coefficients of three-fold of those not successfully achieving the prediction. Lopez & Rees (2001) confirm Skinner & Sloan (2002) and Conrad, Cornel & Landsman (2002) that stock prices react more strongly to negative than to positive earnings shocks. The findings suggest that investors are too optimistic about firms' prospects and, as a consequence, they will penalize firms that do not meet their expected earnings.

Proponents of market-wide regime shifting behavior approach (hereafter, MW approach) believe that asymmetric stock price reaction results from economic condition indicated by high or low market levels. A high market level, on one hand, is defined as

periods of profitable stock market and favorable market-wide news. A low market level, on the other hand, is defined as the periods of unprofitable stock market and unfavorable market-wide news. Conrad, Cornel & Landsman (2002) find that asymmetric stock price reaction to earnings shocks are more pronounced at the high market level. That is, the stock price reaction to negative earnings shocks is stronger at the high market level than at the low market level. This finding is consistent with the systemic shift in investors' sentiment. Namely, when the market level is high, for instance, investors are optimistic in that they expect positive earnings shocks from all firms in the market, not merely from firm-specific. This finding is consistent with MW approach (David, 1997; Veronesi, 1999) and implies that investors feel unsecured about the market condition so that they have to predict the market condition using information from the past.

Both firm-specific and MW approach adequately explains the asymmetric behavior of stock price reaction in well-developed capital markets. Both approaches, however, lack empirical evidence from emerging capital markets. Do both approaches explain the asymmetric behavior of stock price responses in emerging capital markets? This study is designed to answer the questions. Such a study is very important for the following reasons.

First, previous studies in advanced capital markets show mix findings. Some studies show a stronger reaction on positive ES, while others find a stronger reaction on negative ES. In emerging capital markets the magnitude of price fluctuations might be greater than that in advanced markets because stock prices might not reflect firms' fundamental values (Bhattacharya et al., 2000). Second, the impact of earnings announcements in emerging capital markets might not be as strong as that in advanced markets. The reason is that investors in emerging markets are accustomed to a high price volatility so that they do not inteliggently respond to good news as do investors in advance markets. Third, in emerging markets there might be information leakage indicating the existence of insider trading. Therefore, investors have anticipated earnings announcements so that there will be no significant price fluctuations at the announcement date (Huberman & Schwert, 1985).

Fourth, Huberman & Schwert (1985) suggest that there is information leakage in emerging capital markets. Such a leakage is driven by two different types of investors—domestic and foreign investors. They behave differently in gaining stock returns. Domestic investors act to destabilize stock prices (Dvorak, 2005). The proces of destabilzing is driven by their closeness to information sources. Because an information leakage is identified in emerging capital markets, earnings announcements do not positively affect the abnormal returns as well as abnormal trading volume. As a consequence, earnings announcements in emerging capital markets will not convey information contents.

The current study explores whether investors in emerging capital markets react differently to positive and negative earnings shocks. The study contributes to the extant theory of asymmetric behavior by investigating the asymmetric behavior in emerging capital markets and by examining whether the asymmetric behavior results from firm-specific earnings announcements or from market-wide information. Using data from three emerging capital markets—Indonesia, Kuala Lumpur, and Manila Stock Exchanges—from the period of 2002-2007, the study finds that: (i) investors do not react to earnings shocks when the shocks are not separated into positive and negative ones; (ii) when the shocks are separated into positive and negative shocks, data show that investor react to the shocks and that the reaction is stronger to positive than to negative earnings shocks; (iii) both firm-specific and MW approach explains the asymmetric behavior of stock price reaction.

This paper is organized as follows. Section 2 describes theory and hypothesis development, section 3 explains research methods, section 4 analyzes data as well as findings, and section 5 concludes the paper.

2. Theory and Hypothesis Development

Association between Earnings Shocks and Stock Return

Earnings shocks occur when firms' actual earnings announced differ from the investors' or the analysts' predicted earnings (Lakonishok, Shleifer & Vihsny, 1994; Ho & Sequeira, 2007). If firms make adequate earnings, then the recorded net assets increase so that the book values of firms' stocks also increase. Otherwise, if firms suffer from losses, the recorded net assets decrease so that the book values of firms' stock decrease. Therefore, earnings per share should theoretically associate with stock price changes, meaning that whenever earnings shocks occur, the stock price changes in a positive directions. Assuming that investors in emerging capital markets are also rational, we re-test the Basu's (1977) hypothesis that earnings shocks are positively assosicate with stock abnormal returns. The following hypothesis is then proposed.

H$_1$: Investos in emerging capital markets respond postively to earnings shocks.

Asymmetric Reaction to Earnings Shocks

In emerging capital markets, the following characteristics are not uncommon. First, investors are accustomed to high fluctuations in stock prices or abnormal returns. Second, investors often obtain information from inside parties before it is publicly announced, meaning that there is an information leakage (Bhattacharya et al., 2000). Third, there is a tendency thant some investors destabilize stock prices to get excessive returns (Dvoraks, 2005). Fourth, previous studies find that the magnitude of market reaction to positive earnings shocks is

different from that to negative earnings shocks. Some studies find that the magnitude of stock price reaction to positive earnings shocks is larger in comparison to that to negative earnings shocks (Lopez & Rees, 2001; Ho & Sequeira, 2007). Some other studies, however, find that the magnitude of stock price reaction to negative earnings shocks is larger compared to that to positive earnings shocks (Skinner, 1994 and 1997; Soffer, Thiagarajan & Walther, 2000; Conrad, Cornell & Landsman, 2002). Regardless of inconsistent findings, investors are theoretically assumed to be conservative in that they will react more on good news than on bad news (Basu, 1977). Positive earnings shocks, therefore, will lead to stronger reactions than negative earnings shocks will. Assuming that investors in emerging capital markets are conservative, we propose the following hypothesis.

H_2: In emerging capital markets investors' reaction to positive earnings shocks is stonger than that to negative earnings shocks.

Association between Positive Earnings Shocks and Market Level

Stock prices drift would be explained not only by earnings shocks but also by industry growth. Conrad, Cornel & Landsman (2002), for instance, find that stock price increases positively relate to market levels. This finding suggests that the stock price increases (decreases) are driven by industry growth, i.e., the agregate stock price increases in specific industry that result from macroeconomic levels—market-up and market-down.

Both market-up and market-down is indicated by an increase in firms' intrinsic value where the value is measured by price/intrinsic value (P/V). The firms's intrinsic value in this respect could not be determined by price/earnings ratio (P/E). The P/V measure, therefore, is conceptually better than P/E in determining the firms' intrinsic value for reasons that follow. First, it considers firms' growth prospects. Second, it considers firms' cost of capital. In conclusion, use of P/V measure leads to Ohlson's clean surplus theory (Frankel & Lee, 1998; Lee, Myers & Swaminathan, 1999). The P/V measure, as contrast to the P/E measure, is able to reduce the stock overprice. Based on the aforementioned arguments, the following hypothesis is developed.

H_3: In emerging capital markets, the earnings response coefficient of the positive earnings shocks increases along with the P/V market levels.

3. Research Methods

Data and Sample

Samples are drawn from companies listed in three emerging stock markets—Indonesia, Kuala Lumpur, and Manila Stock Exchanges—during the period of 2002-2007. Firms must meet the following criteria to included in the sample: (i) firms operate in manufacturing and financial sectors. Manufacturing sector includes consumptive goods industry, basic and chemical industry, service and investment trading, and others; (ii) firms publish audited financial statement for the period of 2003-2007; and (iii) firms' stocks are actively traded during the period.

Data are taken from OSIRIS Database, Center for Social Study, Universitas Gadjah Mada and consist of daily return data, beta securities correction, and the dates of the earnings statement or financial statements published.

Variables and Measurements
Cumulative Abnormal Return

Cumulative abnormal return (CAR) is the sum of the abnormal returns during the event period. The event period observed in this study is three days period after the dates of the earnings statement. Abnormal return is the difference between the actual return and the predicted return.

$$AR_{i,t} = R_{i,t} - E[R_{i,t}]$$

Notes: $AR_{i,t}$ is the abnormal return of security number-i during the event period t, $R_{i,t}$ is the actual return for the security number-i during the period t, $E[R_{i,t}]$ is the expected return for security number-i during the event period t.

The actual return is the return during the period of t which is the difference between current prices and previous price. Actual return is calculated using the following formula:

$$R_{i,t} = (P_{i,t} - P_{i,t-1})/P_{i,t-1}$$

Notes: $R_{i,t}$ is the return of security i during the period t, $P_{i,t}$ is the market price of the security i during the period t, $P_{i,t-1}$ is the market price of security i during the period $t-1$.

The expected return is calculated using market model. The expected return calculation using market model is conducted within two stages, namely (1) emerging expected model using actual data during estimated periods and (2) using this expected

model to estimate the estimated return during the window periods. The expected model can be developed with the Ordinary Least Square (OLS) regression techniqES using following equation:

$$R_{i,j} = \alpha_i + \beta_i . R_{Mj} + \varepsilon_{i,j}$$

Notes: $R_{i,j}$ is the actual return of the security number-i during estimated period j, α_i is the intercept for the security number-i, β_i is the slope coefficient which is the beta coefficient of the security number-i, R_{Mj} is the market index return during the estimated period j calculated using the formula of $R_{Mj}= (CI_j–CI_{j-1})/CI_{j-1}$, with CI is the Composite Index, $\text{\euro}_{i,j}$ is the residual error of the security number-*i* during the estimated period *j* calculated using market adjusted model.

The next step is the cumulative abnormal return (CAR) calculation using the following formula:

$$CAR_{i,t} = \sum_{a=t3}^{t} AR_{i,a}$$

Notes: $CAR_{i,t}$ is the cumulative abnormal return of the security number-i during the day number-t, which is the accumulated abnormal return (AR) of the security number-i after the event period of (t_{+1}) until t_{+3}, $AR_{i,a}$ is the abnormal return for the security number-i during the day number-a, which begins during t_{+1} (days after event period) until three days of event period (t_{+3}).

Earnings Shocks

According to Ho & Sequeira (2007), earnings shocks are calculated by subtracting forecasted EPS from actual EPS. Then the difference is divided by the closing price during the last day of the trading month before the date of the financial statement published. If the result is positive, the positive earnings shocks occur. Inversely, if the result is negative, then the negative unexpected return occurs.

$$ES = \frac{(AEPS - FEPS)}{P_{t-1}}$$

Notes: ES is the earnings shocks, AEPS is the actual EPS, FEPS is the forecasted EPS.

Size

Consistent with Edward, Benson & Ohlson (1995), Skinner & Sloan (2002), Lopez & Rees (2001), Conrad, Cornel & Landsman (2002), and Ho & SeqESira (2007), this study uses the natural logarithm (ln) of the closing price during the last day of the trading month before the earnings statement, multiplied by the sum of the outstanding stocks in accordance with the financial statement published. This measurement is used as a company size proxy.

The Usage of Market Value Ratio against Intrinsic Value

Conrad, Cornel & Landsman (2002) find that asymmetric reaction of the stock price against positive earnings shocks and negative earnings shocks is affected by economic conditions. The study findings are based on the market level proxy during various economic conditions. High market level is defined as the periods when the economic conditions are profitable and the wide-market news is favorable. Inversely, low market level is defined as the periods when the economic conditions are unprofitable and the wide-market news is unfavorable. To define the market level, Conrad, Cornel & Landsman (2002) used the proxy which is the difference of the ratio of the market price against the current earnings per share (P/E) and the average ratio of the market price against earnings per share during 12 months before.

Unlike Conrad, Cornel & Landsman (2002), the study conducted by Ho & SeqESira (2007) used the ratio of the market price against intrinsic value (P/V) as the proxy of the market level. In this study, Ho & SeqESira state that the P/V usage has a relative predictive ability advantage than P/E as reported by Frankel & Lee (1998). Furthermore, P/V uses more information available about the companies, such as current company value, current expected return on equity (ROE), current return on equity, two years and three years predicted earnings, which serve as the long term company growth prediction. Theoretically, the measure of P/V is better than any other measures. Francis, Olsson & Oswald (2000) find that estimated abnormal earnings is more accurate and able to explain the variability of the equity price better compared to the other variables, such as dividend and free cash flow.

The method used to calculate intrinsic value (*V*) is EBO Residual Income Model. This method has a better capability to calculate the intrinsic value of the stock (Foster, Olsen, & Shevlin, 1984; Bernard & Thomas, 1989, 1990; Chan, Jagadeesh, & Lakonishkok, 1996, 1999). The intrinsic value calculation formula uses EBO model period as described by Frankel & Lee (1998) and Lee, Myers & Swaminathan (1999) as follow.

$$V_{i,t}^2 = B_{i,t} + \frac{B_{i,t}\left(FROE_{i,t+1} - re_{i,t}\right)}{\left(1 + re_{i,t}\right)} + \frac{B_{i,t+1}\left(FROE_{i,t+2} - re_{i,t}\right)}{\left(1 + re_{i,t}\right)^2} \tag{1}$$

At this equation (1), $V^2_{i,t}$ is two estimated EBO periods for the company i during the year of t; $B_{i,t}$ is the par value of each share for the company i during the year t; $re_{i,t}$ is the capital expenditure for the company i during the year t; and $FROE_{i,t+\tau}$ is the annual forecasted ROE for the company i during the year or t during the period $t+\tau$ (during the period $\tau = 1$ until $\tau = 12$).

The input variables required to operate EBO model are forecasted ROE, current par value of each share and predicted value of each share, and company capital expenditure. The forecasted ROE is calculated using the equation 2 as follow.

$$FROE_{t+\tau} = \frac{FEPS_{t+\tau}}{\left(B_{t+\tau-1} + B_{t+\tau-2}\right)/2} \qquad (2)$$

Notes: $FROE_{t+\tau}$ is the forecasted ROE during period $t+\tau$ (during period $\tau = 1$ until $\tau = 2$); $FEPS_{t+\tau}$ is the forecasted EPS during period $t+\tau$ (during notaion $\tau = 1$ until $\tau = 2$); $B_{t+\tau-1}$ is the par value of each share during $t+\tau$ -1; and $B_{t+\tau-2}$ is the par value of each share during $t+\tau$ -2.

The forecasted EPS during period $t+\tau$ is estimated using one-year-ahead ($FEPS_{t+1}$) and two-year-ahead ($FEPS_{t+2}$). The book value used in the EBO model is calculated using equation (3) as follow.

$$B_{i,t+\tau} = B_{i,t+\tau-1}\left(1 + FROE_{i,t+\tau}\left(1 - k\right)\right) \qquad (3)$$

Notes: $B_{i,t+\tau}$ is the book value for the company i during the year $t+\tau$ (for $\tau=0$ until $\tau=1$); $FROE_{i,t+\tau}$ is the forecasted ROE for the company i during the year $t+\tau$ (for $\tau=0$ until $\tau=1$); and k is dividend payment ratio. Because the dividend payment ratio is the percentage of net income paid in the dividend, estimation for certain company in k is calculated by dividing the cash dividend paid during the last year with the net income (EPS multiplied by outstanding share).

Lee, Myers, & Swaminathan (1999) find that the inclusion of interest rate of various time, especially short term interest rate, can increase the V predictive power to predict stock return. Consistent with Lee, Myers, & Swaminathan (1999), this study uses a capital expenditure for certain company to calculate V using equation (4) as follow.

$$E(re_{i,t}) = r_{f,t} + \beta_{i,t}(RP) \qquad (4)$$

Notes: $E(re_{i,t})$ is the expected capital expenditure for the company i during the year t; $\beta_{i,t}$ is the beta for the company i during the year t; and RP is the market risk premium. Even though the V is sensitive against interest rate selection, Lee, Myers, & Swaminathan (1999) find that the effect of market risk premium selection against the V performance can be ignored.

Market Level

The market price ratio between the stock against and intrinsic value (P/V) is used as the market level proxy. Intrinsic value is calculated using Residual Income Model (RIM) approach from Edward, Benson & Ohlson (1995). After the intrinsic value of each stock is calculated, the next step is the calculation of market P/V ratio for each period using the following formula.

$$P\!/\!V_t (market) = \frac{\sum_{i=N_t}[P_{i,t}/E_t(V_i)]}{N_t} \qquad (5)$$

where $P_{i,t}$ is the market price of the stock for the company i during period t; $E_t(V_i)$ is the estimated intrinsic value for the company i during the period t calculated using EBO model; and N_t is the total sum for all companies during the period t. From the all observation periods, the period that have the lowest value of P/V ratio is considered as the low market level, whereas the period that have the highest value of P/V ratio is considered as the high market level.

Hypothesis Testing

Ho & Sequeira (2007) states that the stock price elasticity is measured generally using earnings reaction coefficient. Earning reaction coefficient is acquired from the regression of excess return against earnings shocks for each company. At the following regression equation, the earnings reaction coefficient is the value of nilai a_1.

$$CAR_{it} = a_0 + a_1 ES_{it} + a_2 SIZE_{it} + \sum_{j=1}^{j-1} a_{2+j} DUM\_Ind_{it} + \varepsilon_{it} \qquad (R1)$$

To show the asymmetric reaction against earnings shocks, two indicator variables are added to the regression equation, namely (1) *up,* which is valued as one for positive earnings

shocks and the others are valued as zero; (2) *down,* which is valued as one for negative earnings shocks and the others are valued as zero. The asymmetric impact can be shown using the following second regression equation with b_1 and b_2 which each describes the positive and negative earnings shocks coefficient.

$$CAR_{it} = b_0 + b_1 ES \times UP_{it} + b_2 ES \times DOWN_{it} + b_3 SIZE_{it} + \sum_{j=1}^{j-1} b_{2+j} DUM\_Ind_{it} + \varepsilon_{it} \qquad (R2)$$

At those (R1) and (R2) equations, CAR_{it} is the sum of excess return during three days before and after the date of the earnings statement announced, ES_{it} is the earnings shocks calculated by subtracting actual EPS with forecasted EPS, then divide the result with the closing price during the last trading day at the last month before the earnings statement, $SIZE_{it}$ is the natural logarithm of the market price of the stock during the month before the earnings statement multiplied by the sum of the outstanding stock in accordance with the financial statement published. The market price used in this calculation is the closing price during the last trading day at the last month before the statement issued. $ES \times UP_{it}$ is the product of *ES* and indicator variable *UP*; and $ES \times DOWN_{it}$ is the product of *ES* and indicator variable *DOWN*. An indicator variable named DUM_Ind_{it} is a dummy variable added into the (R1) and (R2) equations to control the impact of industrial sector, which *j* described the three industrial sectors analyzed. Each value of *j*, DUM_Ind_{it} are equal to one when the company is within *j* industrial sector and zero if otherwise. All of the regression equations are estimated among *j-1* industrial sector to avoid dummy variable trap (Gudjarati, 2003), with the formulation as follow.

$$CAR_{it} = b_0 + \tilde{b}_1(ES_{it} \times UP + ES_{it} \times DOWN) + \tilde{b}_2 ES \times DOWN_{it} + b_3 SIZE_{it} + \sum_{j=1}^{j-1} b_{2+j} DUM\_Ind_{it} + \varepsilon_{it} \quad (R3)$$

4. Data Analysis

This study assumes that investors in emerging market forecast future companies' earnings. They, then, evaluate whether the actual companies' earnings meet their expectation. If the actual earnings exceed (do not meet) their expected earnings, then positive (negative) ES occurs. It is rationally expected that the stock price will rise up (go down) if the earnings shocks are positive (negative).

Descriptive Statistics

This study uses three emerging stock markets. i.e., Indonesia, Malaysia, and the Phillipines. Initially, this study collects 1,170 firm-year samples. Due to data incompleteness, this study finally uses 413 firm-year samples. The incompleteness is mainly due to the abscence of earnings announcements (211 firm-years), firms' outstanding shares for the last two years (184 firm-years), closing price during the two last year (126 firm-years), earnings per share during four year observations (185 firm-years), and others (51 firm-years). Table 1 shows descriptive statistics of CAR, UE, size and P/V for full sample.

Table 1 shows descriptive statistics of CAR, ES, size and P/V for full sample. The table also divides samples into positive and negative ESs. In the other perspective, this table classifies the samples between manufacturing, and banking and financial industries. The CAR is the cumulative abnormal return during three days after the date of earnings announcement. The mean of CAR for full sample equals 0.0038 and its standard deviation equals 0.1747. The mean of ES for full sample equals to 50.2882 with standard deviation as 600.9468. The samples that have ES less than zero (ES < 0) has mean of CAR which equals 0.0157 and standard deviation equals 0.1303. Meanwhile, the mean of ES equals -69.1225 with standard deviation equals 236.5798. Otherwise, the sample with ES greater than zero (ES > 0) has mean of CAR which equals 0.0020 and standard deviation equals 0.1879. The mean of ES equals 118.3174 with standard deviation equals 725.1118. The sample of manufacturing industry has mean of CAR which equals 0.0061 and standard deviation equals 0.1782. The mean of ES equals 56.0899 with standard deviation equals 626.6493. The sample of banking and finance industry has the mean of CAR which equals -0.0206 and standard deviation equals 0.1314. The mean of ES equals -10.4681 with standard deviation equals 168.3254.

The descriptive statistics show relatively similar to studies by Ho & Sequeira (2007), Conrad, Cornel & Landsman (2002) and other similar studies conducted by O'Brien (1998); Kang, O'Brien & Sivaramakrishna (1994). These studies show negative signs for ES that is less than zero and positive signs for ES that is greater than zero. These results indicate that the analysis' forecast is mostly optimistic. The table also deduces that negative ES is responded in greater magnitude in comparison with positive ES, showed by greater CAR which equals 0.0157 for negative ES compared to the CAR of positive ES which equals 0.0020. Meanwhile, the sample with negative ES has absolute ES which equals 69.1225, compared to the positive ES which has absolute ES of 118.3174.

Insert Table 1 about here

Firm Specific Model Examination

The first model examination is conducted by regressing full sample into the first regression model. The result of this regression is showed in Table 2 as follows. The result shows that ES has negative value which equals 0.0000 (t-value: 0.3528) which is statistically insignificant. For the sample of manufacturing industry, the association between ES and CAR equals 0.0000 (0.3676) which are also statistically insignificant. The result indicates that positive or negative ES is not associated with CAR. Therefore, hypothesis H1 that states "ES is positively associated with abnormal stock return" is not supported. Similarly, for the sample of banking and financial industry, the earnings response coefficient equals 0.0000 (0.9233) which is statistically insignificant. Meanwhile, the examination result for control variable shows that size is associated positively and significantly with CAR. For full sample, this association has positive slope coefficient of 0.0083 (2.3250) and for manufacturing sample, this association has positive slope coefficient of 0.0077 (1.9988). Both coefficients are statistically significant at level of 5%. This result is inconsistent with the result of study conducted by Ho & Sequeira (2007) who find that both positive and the negative earnings shocks have positive and significant association with abnormal stock returns.

Insert Table 2 about here

With the absence of the association between ES and CAR examined by firm specific model in this first regression model, this study continued to examine all samples with the second and third regression models. The examination results are shown in Table 3 as follows.

Insert Table 3 about here

This table shows that the abnormal return reaction for positive ES is significantly greater than negative ES. This result is marked by the value of b_1-b_2 which equals 0,0001

with *t-value* (b_2 is unequal to zero) of 269.316 which is significant at level of 1%. This result is in accordance with the finding by Ho & Sequeira (2007) and Lopez & Rees (2001) who find that the earnings response magnitude of positive ES is greater than negative ES. Another study conducted by Conrad, Cornel & Landsman (2002) find different result. They find that the earnings response reaction of negative ES is greater than positive ES. The difference of value of the reaction coefficient between positive ES and negative ES indicates that the hypothesis H2 is supported. Therefore, this study concluded that the association between ES and CAR is different for the companies that have positive ES in comparison with the companies that have negative ES.

Table 3 also indicates that the earnings response reaction for positive ES is significantly greater than the reaction for negative ES. This result is consistent with manufacturing industry sample having the value of b_1-b_2 which equals 0,0001 with *t-value* (b_2 is unequal to zero) of 231.374 which is significant at level of 1%. Therefore, this study supports the firm specific approach. Previous study related to firm-specific is Skinner & Sloan (2001) who find that the earnings response reaction for negative ES is significantly greater than positive ES. Another study conducted by Lopez & Rees (2001) which also applying firm-specific model find that the earnings reaction for the company achieved predicted analysis (positive ES) is greater than the company failed to achieve predicted analysis (negative ES). Both Skinner (2001) & Sloan and Lopez & Rees (2001) agree that the magnitude of stock price reaction is stronger for negative ES than positive ES. They suggested that investors' irrationalities who are too optimistic to estimate about future company earnings cause the moment. It is also concluded that they make greater reaction against stock price whenever their expectations is failed.

The regression result per industry sector shows that the reaction against CAR for the companies exceeding investors' prediction (positive ES) is higher coefficients compared to the companies failed to achieve investors' prediction (negative ES). This study finds that the reaction coefficient of positive ES is significantly greater than negative ES. This result is consistent for all industry sectors investigated. Therefore, the firm-specific approach is supported.

Market-Wide Regime Shifting Behavior Examination

Before examining the market-wide regime shifting behavior, the market level differentiation is conducted. This study constructs the data sample by dividing into several portfolios based on P/V value. This study divides classified-random portfolio based on the percentile of P/V per 10%, and below and above the mean of P/V. Table 4 shows the P/V value limitations presented as follows.

Insert Table 4 about here

To examine the market-wide regime shifting behavior approach, this study regresses the sample data according to the market level portfolios. The regression used the second and the third regression models. Table 5 shows the result. It shows that the coefficient of positive ES for each market level at portfolio percentile of 0-10%, 20-30%, 30-40%, 40-50%, 50-60%, 60-70%, below the mean and above the mean is bigger than negative ES. Meanwhile, other results do not show the difference between positive and negative ESs which is statistically significant. However, the examination with greater frequency shows greater earnings response coefficient for the positive ES.

Insert Table 5 about here

The examination result shows that the stock price reaction against positive ES is greater compared to negative ES which is statistically significant. For P/V percentile of 0-10%, the difference of b_1-b_2 equals 0.0003 with t-value of 3.5323 that is significant at level of 1%. This result rises up as the P/V percentile. Percentile of 20-30% has the difference of b_1-b_2 which equals 0.0002 (t-value: 3.3268) which is significant at level of 1%, P/V percentile of 30-40% has the difference of b_1-b_2 which equals 0.0001 (10.4952) which is significant at level of 1%, P/V percentile of 40-50% has the difference of b_1-b_2 which equals 0.0000 (4.8859) which is significant at level of 1%, and it is sill rising up until P/V percentile of 50-60%. Below the mean and above the mean examinations show similar result, that is the difference of b_1-b_2 increases from 0.0002 (15.2467) to 0.0006 (21.1350) which is significant at level of 1%. The increase of market level is shown by the greater response coefficient for above the mean portfolio in comparison to below the mean portfolio. This means that the higher level P/V shows greater stock price reaction.

Based on these findings, different market level shows different reaction against positive ES and negative ES. Therefore, this study suggests that the price and intrinsic companies' value ratio could capture the market level. In other words, hypothesis 3 could be supported that the earnings response coefficient of positive ES rises up as the market level increases. This result is not consistent with the study conducted by Ho & Sequeira (2007)

and Lopez & Rees (2001) who find that the reaction coefficient against positive or negative ESs do not rise up as the market level. Therefore, this study formulate that the market-wide regime shifting behavior approach could be supported.

Findings and Limitations

First of all, this study finds that empirical evidence does not support the hypothesis stating that earnings shocks associate with abnormal returns. This study then divides the earnings shocks into positive and negative shocks and tests whether the diffeent types of shocks associate with abnormal returns. Empirical evidence shows that positive earnings shocks affect abnormal return greater than do negative earnings shocks. This result implies that the firm specific model hypothesis is supported. Therefore, this study concludes that the stock price growth becomes more positive when positive earnings shocks occurred in comparison with negative earnings shocks (Ho & SeqESira, 2007; Lopez & Rees, 2001, and Nwaese, 2000).

The stock price reaction against positive ES increases as the market level increase marked by P/V level. The stock portfolio with higher P/V level is reacted greater. The measurement of this response coefficients are shown even more for positive ES compared to negative ES. Therefore, this study concludes that the market wide regime shifting behavior approach is also supported (Ho & SeqESira, 2007; Lopez & Rees, 2001, and Nwaese, 2000). Inversely, this study rejects the higher stock price reaction against negative ES compared to positive ES (Skinner & Sloan, 2001; Conrad, Cornel & Landsman, 2002; O'Brien, 1998); Kang, O'Brien & Sivaramakrishna, 1994).

This study finds that magnitude of stock price reaction does not only reacts dominantly against positive ES, but does not also react negatively against negative ES. The examination result using first, second and third regression models did not show the reaction against positive ES. Therefore, earnings announcements do not give positive sign to the investors at the emerging stock market. The market drift at emerging capital market is not supported by the earnings announcement, but more affected by the condition of the capital market itself. The stock market condition represented by P/V level, which is actually also P/E level, is more able to show the movement of stock market determined by the market sentiment at the point of companies valuation. Therefore, this study suggests that the investors' aggregate belief to the fundamental value of company by company is able to drift the stock price at emerging market. Thus, the determinant factors lies more on intrinsic values of the company (Frankel & Lee, 1998; Lee, Myers & Swaminathan, 1999; Francis, Olsson & Oswald, 2000; Foster, Olsen, & Shevlin, 1984; Bernard & Thomas, 1989, 1990; Chan, Jagadeesh, & Lakonishkok, 1996, 1999).

The last finding, this study suspects the possibility of information leakage of earnings announcement. This suspicion comes from the result of the first examination that the association of CAR and ES is not proven. The measure of abnormal return which is statistically insignificant during t_{+1} until t_{+3} shows that earnings announcement have been possibly previously responded by the investors. Therefore, the investors' expectation against future earnings becomes excessive compared to the abnormal return. This excessive expectation affects the variance of future expected earning and the variance of abnormal return which moves in imbalance. This condition also shows the tendency of market inefficiency that does also affects the absence of information content in every earnings announcements. Other study shows equally to prove that earnings news announcements are not really an event. The proposed reason is the possibility of the stock market in inefficient form implied that the stock prices are not always associated with the companies' intrinsic value (Bhattacharya et al., 2000). Furthermore, the new news announcements have been completely anticipated during the previous periods (Huberman & Schwert, 1985).

This study has various limitations that compromise its ability to predict and explain accurately. *First*, the limits of available sample observed and the observed short-period. This occurs because the exclusion a lots of data due to incompleteness. This incompleteness is mainly due to the absence of earnings announcements, firms' outstanding shares for the last two years, and closing price during one last year. Considering this limitation, it is necessary for further studies to obtain more samples and for longer period so that the result becomes more valid.

Second, the EPS and ROE forecast are statistically manipulated. This forecast could be different whenever compared to the US stock market, where analysts do the forecast. Therefore, the forecast in this study can be considered to be too rough. *Third*, the study window width within this study equalizes with the earnings shocks study at the advanced stock market. The window width selected in this study is three days from t_{+1} until t_{+3}. The consequences of this window selection may ignore any other information having effect against abnormal return. The examination employing intraday data should be more able to answer the earnings announcements drift within the minute or hour period.

Forth, market level measured by the formula of P/V_t which is a new approach is still need to be considered more deeply. This proxy serves as a replacement of price and earnings ratio (P/E ratio). The reason to apply the above formula is that the validity of V_t value which also serves as the indicator of company's intrinsic value. The classification of market level based on free-random portfolio should make better result for the market level examination. Similarly, future study could identify company classifications that are able to derive the better conclusion than this study. Market level should be formulated with the

consideration of the actual market condition by investigating the market condition whether it is during market-up or market-down. ***Finally***, the result inferred from this study is still not able to answer the investors' interests who observe directly the current condition of emerging market. The investors' interests could only be answered and whether the stock market performance is explained by some similar study within longer duration.

5. Conclusion

Assuming that investors in emerging stock markets forecast company's future earnings, this study concludes that their forecasts are too optimistic. It is highlighted by earnings shocks (ES) that have positive values. This study shows that there is no positively significant association between earnings shocks and the stock price reactions indicated by CAR. The association indicates that the stock price does not react to the information signs, either positive or negative earnings shocks moments. This might be results from information leakage occurring in emerging stock markets of Indonesia, Malaysia, and Philippines.

This study supports the firm specific model hypothesis stating that the association between ES and CAR is different between companies with positive ES and those with negative ES. This is shown by the stronger coefficient of stock price change moment caused by positive earnings shocks is greater than the one caused by negative earnings shocks. This result is consistent with and dominantly documented for all observed industrial sectors, so that firm-specific approach is empirically supported and could be applied in emerging stock markets.

The examination result indicates that market-wide regime shifting behavior approach is also empirically supported for emerging stock markets. The market level examination also shows difference in the reaction to positive ES and negative ES. It could be concluded that the measurement of market reaction movement captures the market level. The market-wide regime hypothesis is supported because the coefficient of positive ES reaction increases as the market level increases. This result is inconsistent with that of previous studies.

Finally, this study finds that earnings announcements do not give positive sign or good news to the investors in emerging stock markets. The stock price drift in emerging capital market is not supported by the earnings announcement sign, but it is more affected by the condition of the market itself. The condition of stock market refers to the investors' belief to the overall company intrinsic value. Therefore, this study suspects the possibility of information leakage on every earnings announcement. Earnings announcements have been responded previously by the investors in emerging capital markets before the date of the announcement. This condition also suggests the markets are inefficient tendency and the absence of informational content on every earnings announcement. The explanation of this occurrence shows equally that the earnings announcements are not really an event. It is

probably caused by the new news announcements that have been fully anticipated or because of the existence of insider trading in emerging capital markets.

HAVE THE ECONOMIC EFFECTS OF JAPANESE CORPORATE MERGERS CHANGED?

Yoshitaka OHASHI, The University of Aizu Junior College Division
Mioko TAKAHASHI, Takasaki City University of Economics

Abstract

Since the late 1990s, the number of Mergers and Acquisitions (M&A) increased rapidly in Japan. One large reason for the wake for M&A wave can be attributed to a series of revision on commercial code, antitrust law and accounting systems. These institutional changes encouraged Japanese firms facing a long economic recession and increased market competition to reorganize business through M&A.

The purpose of this paper is to investigate whether the economic effects of mergers have changed since the M&A related institutional revision started in Japan. By comparing the stock price reaction and financial performance of 73 merger cases conducted from 1986 to 1999 and 72 merger cases conducted from 2000 to 2004, we investigate whether the effects of mergers have changed between the two periods. We also try to contribute to this literature by investigating the relation between stock price reaction at merger announcement and post merger financial performance.

Our main findings are summarized as follows. First, contrary to positive cumulative abnormal returns for both acquiring and target firms from 2000 to 2004, cumulative abnormal returns for acquiring and target firms during 1984 to1999 were at best zero or negative. Second, mergers conducted from 2000 to 2004 caused negative impact on ROE and sales growth rate while merger conducted from 1986 to 1999 had no impact on financial performance. Third, we did not find evidence to support any specific relation between market reaction and financial performance changes during the 1986 to 1999 period. On the other hand, when we focus on mergers conducted from 2000 to 2004, we find evidence to support negative relation between stock return and change in ROE.

Key Words: Corporate merger, Market Reactions, Financial Performance

1. Introduction

It is well known that Japanese corporate culture and business practices have long made the market for corporate merger and acquisition (M&A) small. For example, the practice of inter-corporate shareholdings made the market for takeovers nonexistent. Most of the mergers in Japan were 'rescue oriented merger' that it occurred when financially distressed company needs to be bailed out by financially sound one.

But this picture has changed since the late 1990s and the number of M&A increased rapidly in Japan. Because of long economic recession and increased market competition, Japanese companies faced a sharp downturn in profitability. To overcome this situation, companies tried to reorganize business through M&A. Also, a series of revision on commercial code, antitrust law and accounting system supported firms to facilitate business restructuring though M&A. Due to this wake for M&A wave, the economic effect of M&A receives greater attention ever before in Japan.

The purpose of this paper is to investigate whether the economic effects of mergers have changed since the M&A related institutional revision started in Japan. By comparing the stock price reaction and financial performance of 73 merger cases conducted from 1986 to 1999 and 72 merger cases conducted from 2000 to 2004, we investigate whether the effects of mergers have changed between the two periods. We also try to contribute to this literature by investigating the relation between stock price reaction at merger announcement and post merger financial performance.

The remainder of the paper is organized as follows. Section 2 reviews prior studies. Section 3 descries the data and methodology. Section 4 presents the main empirical results. Section 5 concludes.

2. Prior studies

To evaluate the economic effect of M&A, prior studies have used two approaches. One approach is to focus on stock returns around the period surrounding the announcement of the transaction. This approach is regarded to be forward looking on the assumption that stock prices are the present value of expected future cash flows. When market regards M&A as value creating transaction, we expect to observe significantly positive abnormal stock returns around the announcement date.

The U.S. evidence shows that target firms' shareholders gain from significantly positive abnormal stock return, while abnormal returns to bidders are at best close to zero or negative (Jensen and Ruback, 1983; Asquith, 1983; Andrade et al., 2001). In short, most of the premiums gained from M&A are attributed to targets' shareholders. The Japanese evidence shows somewhat different picture. Pettway and Yamada (1986) examined abnormal returns from M&A cases in Japan completed between 1977 and 1984. Although both are not statistically significant, target firms' share showed negative (-0.07%) abnormal return, while bidders' share showed positive (+0.82%) abnormal return. Usui (2001), by using M&A cases completed between 1989 and 1999, reported significant[28] positive

---

[28] at 10 % significance level

abnormal return for both target (+4.08%) and bidders (+1.62%) shareholders. This evidence is supported by Inoue (2002) which also reported significant[29] positive abnormal return for target (+4.37%) and bidders (+1.51%) shareholders, by using a sample of transactions between 1990 and 2002. These evidences show that while abnormal returns to target and bidders are at best close to zero or negative until the mid 80s, both target and bidders' shareholders receive premium from M&A since the late 1990s in Japan.

Another approach to evaluate the effect of M&A is to compare the reported financial performance before and after M&A. The results of M&A effects on financial performance are mixed. Ravenscraft and Scherer (1989), Herman and Lowenstein (1988) examined earnings performance after takeovers and reported that merged firms have no operating improvements. On the other hand, Smith (1990), Healy et al. (1992) and Cornett and Tehranian (1992) reported an improvement in profitability after merger. The reason for this inconsistency may be due to methodological problems, different sample size and investigation period. However when focusing on Japanese cases, the evidence shows that merging firms' financial performance (profitability and growth) declines after merger (Muramatsu, 1986; Odagiri and Hase,1989).

Evidence from prior research shows that although financial improvements after M&A are not observed, it seems that both target and bidders' shareholders receive premium in Japan. We will try to contribute to this literature by investigating the relation between stock price reaction at merger announcement and post merger financial performance.

3. Research design

3.1 Sample

We collect merger cases of Japanese listed companies that were completed from 1986 to 2004. We used data book published by RECOF Corporation[30] to collect merger cases. Mergers that failed and mergers involving financial institutions (bank, security and

---

[29] at 10 % significance level
[30] RECOF Corporation ed. 2008. *Data book about M&A on Japanese firms: 1985-2007*. RECOF Co. (in Japanese)

insurance) were excluded from the sample. This made our sample size to 145 merger cases with a total of 151 target firms.

Because of the institutional and environmental change surrounding M&A, we infer that motivations for and economic effect of merger among Japanese companies have changed. To test this hypothesis, we divided our sample into 2 periods (groups) based on the year when merger was conducted. The first sample group consists of mergers completed from 1986 to 1999 and the second sample group consists of mergers completed from 2000 to 2004.

Panel A in table 3.1 shows the number of mergers completed each year during our sample period. 73 out of 145 merger cases in our sample were conducted from 1986 to 1999 and 72 cases were conducted from 2000 to 2004. We can see from this figure that the number of merger cases increased rapidly after year 2000.

Panel B in table 3.1 shows the industrial distribution of merged firms. Most of the firms merged during 1986 to 1999 belong to commercial business (trading and retail), service, ceramics, electronics, machine, and pulp. On the other hand, most firms merged between 2000 and 2004 belong to commercial business, construction, service, nonferrous metal, and machine.

[Table 3.1 about here]

3.2 Market reactions to the announcement of mergers

To see whether the economic effect of merger changed, we first investigate stock price reaction to the announcement of mergers. We compute abnormal returns occurring between day -10 and day +10 (day 0 is the announcement date) by subtracting the daily return of the market index (TOPIX) from the daily return of each firm. In addition to abnormal returns, we compute cumulative abnormal returns for the three (eleven and twenty-one)

trading days window centered on the date of the announcement of mergers.[31] If shareholders perceive merger as value creating (deteriorating) activity, then positive (negative) abnormal returns will expected to be observed.

The main purpose of the paper is to see whether there are any difference in the economic effect of merger conducted in the period from 1986 to 1999 and the period from 2000 to 2004.[32] If we observe significant mean difference between these two periods, it means that economic effects of merger have changed.

Stock price for each firm and market index (TOPIX) are collected from the Stock Price Data CD-ROM (TOYOKEIZAI Inc.) and the daily Japan financial newspaper.

3.3 Merger effects on financial performance

Next, we investigate financial performance changes from pre to post merger. We use six performance indexes based on financial statement data: return on asset (ROA), return on equity (ROE), operating cash flow (OCF), sales growth rate, cost of goods sold to sales ratio, and labor cost to sales ratio. These ratios are computed as follows.

$$ROA = \frac{(Operating\ income + Investment\ gain + Interest\ and\ dividend\ income)}{Total\ assets\ (average)}$$

$$ROE = \frac{Net\ income}{Equity\ capital\ (average)}$$

$$OCF = \frac{(Operating\ income + Depreciation\ and\ amortization)}{Total\ assets\ (average)}$$

$$Sales\ growth\ rate = \left(\frac{Sales\ for\ current\ year}{Sales\ for\ prior\ year}\right) - 1$$

$$Cost\ of\ goods\ sold\ to\ sales\ ratio = \frac{Cost\ of\ goods\ sold}{Sales}$$

$$Labor\ cost\ to\ sales\ ratio = \frac{Labor\ cost}{Sales}$$

$$Tobin's\ q = \frac{(Total\ liabilities + Market\ value\ of\ equity)}{Total\ assets} \quad \left(Tobin's\ q\ (year\ 0) = 100.\right)$$

---

[31] The cumulative abnormal returns are calculated by adding the abnormal returns for the three (eleven and twenty-one) days.

[32] The null hypothesis is that the mean difference of the (cumulative) abnormal returns for the acquiring (target) firms between mergers in the period from 1986 to 1999 and in the period from 2000 to 2004 equal zero.

Because accounting income is affected by accounting policy choice, Healy et al. (1992) argued to use operating cash flow (*OCF*). For this reason we use OCF to measure profitability besides accounting income (*ROA* and *ROE*). We also use *sales growth rate*, *cost of goods sold to sales ratio*, and *labor cost to sales ratio* as a measure for growth and efficiency (cost reduction).

To compare with post merger performance, we develop pre merger performance measure by aggregating targets' financial data to acquiring firms' one. Comparing the post merger performance with this benchmark provides a measure of the change in performance. But, as Healy et al. (1992) notes, some of the difference between pre and post merger could be also due to economy wide and industry factors. To control for these factors, we use industry-adjusted performance measure. This is calculated by subtracting the industry average from the sample firm's performance measure.

After computing the industry-adjusted performances for each merger case, pre merger (years -3 to -1) performance mean are subtracted from the post merger (years +1 to +3) performance mean. To see whether the observed numbers are statistically significant, we conduct a parametric test (t-test).

We also calculate Tobin's q at the end of each accounting period during years 0 to +3. Tobin's q at year 0 will be replaced as 100. Also, the q ratio for years +1 to +3 will be replaced accordingly. Based on these numbers, post merger (years +1 to +3) mean of Tobin's q ratio would be computed. The change in q ratio would be obtained by subtracting 100 from the mean.

We compute mean difference of these performance changes both for mergers conducted in the period from 1986 to 1999 and mergers conducted in the period from 2000 to 2004.[33] If we observe significant mean difference, and conduct the parametric test (t-test), this implies that merger effects have changed between these two periods.

---

[33] The null hypothesis is that the mean difference of the merger effects between mergers in the period from 1986 to 1999 and in the period from 2000 to 2004 equal zero.

Firms' financial data are obtained from NEEDS financial database (Nikkei Digital Media, Inc.). Table 3.2 shows the means and standard deviations of financial performance before subtracting the industry average.

[Table 3.2 about here]

3.4 Relation between market reactions and financial performance changes

Finally, we investigate the relation between market reactions and financial performance changes. Our aim here is to see whether there is a significant relation between positive (negative) cumulative abnormal return and positive (negative) financial performance change.

We classify the sample for each group into 2×2 matrix base on stock price reaction and financial performance change. We use each firm's cumulative abnormal return as a surrogate for market reaction and separate the sample based on its sign (positive or negative). Changes in ROA, ROE, OCF, and Tobin's q after merger is used as a measure for financial performance change. These measures are also divided into two groups based on its sign (positive or negative). Chi square test is conducted to see the relation between market reaction and firm performance.[34]

4. Results

4.1 Results of examining market reactions

Table 4.1 shows the results of stock price reactions of acquiring firms. Panel A reports abnormal returns for 11 days (from day -5 to day +5), and Panel B shows cumulative abnormal returns for 3, 11, and 21 days, respectively.

For acquiring firms in the 1986 to 1999 period, abnormal returns for second and third day after the announcement (day +2 and +3) and cumulative abnormal returns for 11 days are significantly negative (the t-statistics shown in table are parentheses). On the whole,

---

[34] The null hypothesis is that the market reaction and financial performance changes are independent.

these results imply that market regard mergers conducted in 1986 to 1999 period as value deteriorating.

The signs of abnormal returns for acquiring firms in the 2000 to 2004 period are mixed. Statistically significant positive abnormal returns were observed for day -1 and 0 and negative abnormal return was observed on day +2. Cumulative abnormal return is significantly positive at 10% level. This result is different from the first sample group in that market regarded mergers as value creating.

Mean differences of each period's cumulative abnormal returns for 3 and 11 days are significant at 5% and 10% level. Compared to negative cumulative abnormal returns in the 1984 to 1999 period, those in the 2000 to 2004 period are positive. This implies that investors show more favorable reactions to mergers in the later period than the former ones.

[Table 4.1 about here]

Table 4.2 shows the results of stock price reactions of target firms. In the 1984 to 1999 period, abnormal returns and cumulative abnormal returns of target firms are not statistically significant. On the other hand, for mergers in the period from 2000 to 2004, positive abnormal returns from day -2 to day 0 and negative abnormal return for day +2 are significant. Cumulative abnormal returns for 3 and 21 days are significantly positive at 1% and 10% levels. This result implies that the market as a hole see mergers as value creating.

Mean differences of each period's cumulative abnormal returns for 3 days are significant at 1% level. Compared to negative cumulative abnormal returns in the 1984 to 1999 period, those in the 2000 to 2004 period are positive. This implies that target firms shareholders show more favorable reactions to mergers in the later period than the former period.

[Table 4.2 about here]

4.2 Results of examining financial performances

Table 4.3 shows the effect of merger on financial performance and the difference of those between the two periods. Row (a) and (d) show premerger performance indexes which

were computed by aggregating target and acquiring firm's financial data. Post merger performance indexes are shown in row (b) and (e).

Row (c) and (f) show the impact of merger on financial performance (merger effect) which is computed by subtracting premerger performance index from post merger ones. To control for economy wide and industry factors, these indexes are adjusted by industrial average ratio. Result in row (c) indicates that mergers conducted during 1987 to 1999 did not cause any economic impact on financial performance. On the other hand, row (f) reports that mergers conducted from 2000 to 2004 have negatively impacted ROE and sales growth rate.

Row (g) reports whether the impact of merger on financial performance are different in the two periods. Positive numbers in profitability (ROA, ROE, and OCF) and Sales growth rate mean that mergers conducted in 1986 to 1999 have more positive financial effects than the mergers conducted in 2000 to 2004. Opposite to these performance measure based on financial statement, Tobin's q improved during 2000 to 2004 period.

[Table 4.3 about here]

4.3 Results of examining the relation between market reactions and performance changes

Table 4.4 shows the results of the chi square test which examined the relation between market reactions and financial performance changes. We use each firm's cumulative abnormal return for 3 and 11 days as a surrogate for market reaction and classified the sample based on its sign (positive or negative). The top left cell with "14" means that 14 firms had negative cumulative abnormal return and ROA declined after merger.

Panel A shows that during the 1986 to 1999 period, we did not find evidence to support the relation between market reaction and financial performance changes. When we

focus on mergers conducted during 2000 to 2004 (panel B), we find evidence to support negative relation between cumulative abnormal return and ROE. A possible explanation for this result is that more than 3 years will be needed for financial performance to improve after merger.

<center>[Table 4.4 about here]</center>

5. Conclusion

The purpose of this paper is to investigate whether the economic effects of merger have changed. By comparing the stock price reaction and financial performance of 73 merger cases conducted from 1986 to1999 and 72 merger cases conducted from 2000 to 2004, we investigate whether the effects of merger have changed between the two periods. We also try to investigating the relation between stock price reaction at merger announcement and post merger financial performance.

Our main findings are summarized as follows. First, contrary to positive cumulative abnormal returns for both acquiring and target firms during 2000 to 2004, cumulative abnormal returns for acquiring and target firms during 1984 to 1999 were at best zero or negative.

Second, we did not find evidence to support that mergers conducted during 1986 to 1999 caused any effect on financial performance. However, mergers conducted during 2000 to 2004 caused negative impact on ROE and sales growth rate.

Third, we did not find evidence to support any specific relation between market reaction and financial performance changes during the 1986 to 1999 period. On the other hand, when we focus on mergers conducted during 2000 to 2004, we find evidence to support negative relation between cumulative abnormal return and ROE. A possible explanation for this result might be that more than 3 years will be needed for financial performance to improve after merger or financial performance did not improve as marked expected.

IMPACT OF QUARTERLY DISCLOSURE ON INFORMATION ASYMMETRY: EVIDENCE FROM TOKYO STOCK EXCHANGE FIRMS

Keiichi Kubota, Chuo University
Kazuyuki Suda, Waseda University
Hitoshi Takehara, Waseda University

Abstract

We investigate whether quarterly disclosure reporting requirements issued by the Tokyo Stock Exchange on April 1, 2004, the related Financial Instruments and Exchange Act of Japan, and the new quarterly accounting standards helped reduce the degree of private information-based trade for listed stocks utilizing the PIN variable proposed by Easley et al. (1996, 2002). We find that it is indeed the case and that there are significant differences between firms which issued quarterly reports by abiding by the exchange rule and firms which did not. We find that such a difference is strongly related to the differences in the estimated liquidity measures of these stocks. Our paper sheds light on the distribution of private information in the Japanese stock market after the disclosure rule is introduced, which is a new finding.

1. Introduction

Next to the abundant evidence on asset pricing for U.S. data, there is a large amount of empirical evidence on Japanese stock market and financial data. As far as the authors are aware, however, there is no study that investigates the role of interim financial disclosure in stock price discovery processes using microstructure data. In a recent review article, O'Hara (2003) emphasizes the importance of exploring the price discovery process before investigating the asset pricing framework. The studies by Easley et al. (1996, 2002) are examples which explore this price discovery process using tick-by-tick U.S. data. They estimate the so-called "PIN" variable, which is a variable related to the probability of information-based trades among all trades.

The Tokyo Stock Exchange requires disclosure of quarterly financial reports since fiscal year 2003 for firms whose stocks are listed in its first and second sections. This requirement, however, is without enforceable penalty even if firms choose not to disclose. Moreover, the new accounting quarterly disclosure standards established March 14, 2007, along with the new Financial Instruments and Exchange Act of Japan enacted September 30, 2007, require disclosure of quarterly financial statements with auditors' reviews from fiscal year April 1, 2008, which has completely changed the previous requirement of semi-annual reporting with certified accountant audits in Japan.

In this paper we use daily tick-by-tick data of firms listed on the Tokyo Stock Exchange and investigate the impact of the introduction of this quarterly disclosure requirement by the TSE upon informational asymmetry in the capital market. For this purpose we use the PIN variable proposed by Easley et al. (1996, 2002) and investigate whether this

new disclosure requirement helped improve distributions of public information versus private information among all trades in the market.

In view of the fact that the majority of countries do not require quarterly reports, including the U.K., France, Germany, Australia, and Hong Kong, this paper gives researchers important insights into the possible impact of new quarterly report requirements on the working of informational efficiency in capital markets.

Section 2 raises our motivation with a discussion on related previous studies, and explains the basic model. Section 3 explains the data and reports basic statistics. Section 4 reports our main empirical results and Section 5 concludes. Appendix A explains the PIN model in detail and Appendix B reports the estimation result from Duarte and Young's (2009) three stage model that allows for systematic information arrival.

2. Our Research Design

2.1 New Quarterly Reporting Regulations in Japan

The Tokyo Stock Exchange requires firms listed in its first and second sections to disclose quarterly reports since fiscal year April 1, 2003. Preceding this requirement, the TSE announced in June 2002 that the exchange would begin to ask firms to disclose quarterly reports on a gradual basis, and issued a formal statement that required firms to disclose condensed quarterly reports starting April 1, 2003. Initially, however, there was no legal penalty even if firms chose not to disclose financial statements, and we can safely say that this requirement was not strictly enforceable at that time. With the enactment of the new Financial Instruments and Exchange Act in 2008, a Japanese equivalent of the Sarbanes-Oxley Act, firms have to disclose quarterly financial statements based on new Japanese Accounting Standards. That requirement began with fiscal year April 1, 2008. These quarterly financial statements are published with auditors' reviews as in the U.S., and they are substituted for previously reported semi-annual financial statements with certified accountants' audits.

TABLE 1 ABOUT HERE

Table 1 shows the percentage of firms which submitted their quarterly reports to the Tokyo Stock Exchange in the first quarter (April to June) and the third quarter (September to December), starting in fiscal year 2001. More than 90 percent of Japanese firms have a March 31 fiscal year-end, and the quarter starts April 1. During the first few years these firms disclosed on a voluntary basis.[35] The sample in the table is the firms we use for our later statistical tests, and we exclude the firms whose fiscal year-end is other than March 31. The sample also excludes firms whose Amihud (2002) measure could not be computed, which we will use in a later part of this paper. The maximum number of firm observations is 2,127 for the second quarter of 2003 and the minimum is 1,282 for the first quarter of 1998.

---

[35] However, in the new emerging market of the "Mothers" at the Tokyo Stock Exchange, quarterly disclosure was required from November 1999.

The third column of the table shows the percentage of firms which disclose the quarterly reports as required by the Tokyo Stock Exchange, the fifth column shows the same percentage of firms listed in the first section, and the last column shows the percentage of firms listed in the second section. We find that only a small percentage of firms disclosed their quarterly reports in fiscal years 2001 and 2002. Since fiscal year 2003 when the stock exchange required the quarterly disclosure, we find that more than 70 percent of firms began to disclose their quarterly reports. For first section firms, these fractions are between 72.7 and 76.5 percent in fiscal years 2003 to 2007, and for second section firms the corresponding numbers are between 60.8 and 70.37 percent. The percentages increased over time for both cases. The difference of the percent between first and second section firms indicates that first section firms with a larger capital base tend to report more willingly than smaller second section firms, but the difference is only about 6.1 percent (76.5 vs. 70.4 percent) in the most recent third quarter of 2007.

Overall, during our sampling period, after fiscal year 2003, about 70 percent of firms disclosed quarterly reports. The increase in the percentage of firms which disclose may reveal interesting time-series data to assess the effect of this disclosure requirement on the working of the stock market in Japan. Moreover, we investigate how degrees of private information-based trades of firms' stocks are different between firms which disclose quarterly reports and firms which do not. In this way, our study can highlight the degree of private information-based trade and accompanying differences in stock liquidity in trading during the time when the new disclosure was introduced into the market.

2.2 Motivation and the Hypotheses

The existence of informational asymmetry among traders in everyday trading is a *de facto* phenomenon even when we accept that the efficient market hypothesis holds for a longer time span. For U.S. data, Easley et al. (1996, 2002) estimates parameter values of the probability of private information-based trades for each day's trading with tick-by-tick data, and similarly, for Japanese data, Kubota and Takehara (2009a) report comparable estimates using tick-by-tick data. These estimated values of the so called PIN variables, which purportedly reveal the probability of private information-based trades, are around 20 percent for mean estimates for these two countries, which support our initial statement in the paper that there exist informational asymmetry in everyday trading of U.S. and Japanese stock markets.[36]

By using microstructure tick-by-tick data for Japan, the main focus of our paper is whether the introduction of new capital market regulations of the quarterly disclosure rule for Japan affects the distribution of private information-based trade relative to public information trade. The motivation to study the impact of the new disclosure regulation rule is similar to previous studies on Regulation FD for the U.S. case by Duarte et al. (2008) and Ahmed and Schneible (2007).

---

[36] In Holden and Subrahmanyam (1992) private information is revealed immediately when the trading interval approaches zero in their microstructure model, but empirical results explained in the main text of this paper indicate that is not necessarily the case for U.S. and Japanese stock markets.

313

However, when one can observe informational asymmetry in capital markets and whenever new disclosure regulations are introduced, benefits for individual investors, firms, and accountants need to be compared with additional costs incurred by all agents involved. That is, one has to inquire whether there is positive value added from newly disclosed information (Demski, 1972, p.66, and Proposition 5). However, social consequences are generally impossible to assess due to Arrow's impossibility theorem (Demski, 2003, pp. 429-431). Thus it is difficult to judge whether new disclosure has moved the economy into Pareto improvement.[37] Moreover, Feltham and Christensen (1988) demonstrate that external reporting provides a basis for Pareto improvement only if those reports lead firms to better production decisions, and that the revelation of firm-specific risk does not matter much when investors are well-diversified. In spite of these negative views on the effective assessment of the new disclosure rule, we still believe in the efficiency of competitive equilibrium when private information eventually gets fully impounded into the rational expectations equilibrium price (Hellwig, 1980, Kyle 1985). That being the case, both the identification of the *ex ante* degree of the existence of private information in the price discovery process (O'Hara, 2003) and the quantitative assessment of the *ex post* changes triggered by the introduction of the new regulation rule are worthwhile queries to be empirically explored.[38] This is the main purpose of this study and we employ the PIN concept for this purpose.

First, we state our first two hypotheses:

*H*1: *As the new quarterly reports begin to be disclosed in capital markets, the probability of private information-based trade will decrease.*

*H*2: *The firms which report quarterly financial statements are accompanied by lower probability of private information-based trade than are firms which do not report.*

We also infer that the degree of informational asymmetry is strongly related to the liquidity of the stock, because informational asymmetry means there is wider disagreement among traders about the true quality of the firm, which triggers wider spreads of limit price orders, and also may even restrain traders from trading stocks if there exists too much uncertainty about the true quality of the firm. Easley and O'Hara (2004), for example, demonstrate within their rational expectations equilibrium model that stocks with higher private information weights reach lower equilibrium prices and thus, an *ex ante* higher cost of capital to compensate for this information risk (Diamond and Verrecchia, 1991). In the context of interim reporting, Yee (2004) constructs a microstructure model with market makers, analysts, and liquidity traders, and shows (*ibid.*, Proposition 3) that increasing reporting frequencies improves the stock liquidity at each announcement date.

---

[37] The proposal from the aspect of the equity concept is conducted by Lev (1988) with regard to the accounting policy context. It is outside the scope of this research.

[38] Note that Laffont (1985) also demonstrates that *ex post* fully revealing rational expectations equilibrium is *ex post* Pareto optimum.

In microstructure studies it is widely assumed that the more illiquid stocks have higher risk and hence higher *ex ante* expected returns (O'Hara, 1995). So we also look at the relationship between private information-based trade and the stock liquidity from this aspect.

Thus, based on the PIN variable we raise our third hypothesis:

*H*3: *When the probability of private information-based trade of a stock decreases, the liquidity of this stock will increase.*

Once again, we are only interested in identifying the association and will not make any further value judgments even if we find evidence to support our hypothesis *H3*. In order to do that, we need to use the correct form of asset pricing theory to control for systematic risks of stocks and it is outside the scope of this research.[39] This is not the main purpose of the paper and our research focus is identifying the distribution of private information-based trades and their changes relating to the introduction of new disclosure regulation rules. It will also give us a clue to identify the price discovery process of stock trading in Japan in relation to the new disclosure rule. Furthermore, it will give us insight into investigating how changes in private information-based trade are related to stock liquidity measures. In this sense our research is purely descriptive but at the same time it provides us with an important insight about changes in the informational structure of capital markets triggered by the introduction of a new disclosure regulation.

One question remaining is whether the frequency of disclosure increases the informational uncertainty. It is outside the scope of this research because we will not investigate the price and/or volume reactions on and around the announcement dates of quarterly reports. However, we cite evidence by Mensah and Werner (2008) which shows that price volatility is higher in countries with a quarterly reporting environment like the U.S. and Canada than in countries with a semi-annual reporting environment like the U.K. and Australia.[40] Also, Atiase et al. (1988) raise the issue of timeliness of financial reports and find that it is strongly related to size, and that a longer delay is associated with smaller price reactions, suggesting more information inflow from other channels. So it seems that more timely disclosure increases price volatility. But again, this is outside the scope of this research.

2.3 Previous Studies on PIN and Interim Reports

The most pertinent study related to the current paper is Duarte et al. (2008). They use the estimated PIN variable as a proxy variable to measure the degree of informational asymmetry and find that the Regulation FD affects the cost of capital, using the PIN variable with other control variables. In Duarte et al. (2008) the estimated PIN and other variables are used as independent variables to predict

---

[39] Recently, Kubota and Takehara (2009b) addressed this issue and found that both the systematic component and the idiosyncratic component of liquidity risk are significant to explain stock returns.
[40] In an early article, May (1971) finds that the price-change response to quarterly earnings was less, but not significantly less than the response for annual earnings.

changes in the cost of capital of firms after the Regulation FD was introduced in 2000. Their main finding was that NASDAQ firms were more strongly affected and costs of capital for these firms increased, suggesting that smaller firms bear more increased costs due to the new disclosure rule.

In other PIN related studies, Vega (2006) analyzes both the behavior of the post announcement return drifts and changes in the PIN variable around the earnings announcement dates with U.S. data. She finds that the order arrival rate is more important than degrees of private information in explaining post-announcement drifts. In other studies, the relationship between the PIN variable and the order placement strategy is analyzed by Ellul et al. (2003) with NYSE data and the relationship between the PIN and credit rating as public information is analyzed by Odders-White and Ready (2003), again for U.S. data.

For the Paris stock market, Atkas et al. (2003) investigates informational effects of corporate events like mergers and acquisitions using the PIN variable. As for the Japanese evidence, Kubota and Takehara (2009a) estimate the PIN values for Tokyo Stock Exchange firms and report the comparable parameter values for Japan with U.S. firms estimated by Easley et al. (2002). These results confirm the robustness of PIN estimates across international markets with different market designs.

For empirical evidence on quarterly report disclosure and the effect of the timing of the interim reports, the former goes back to the late 1960s using U.S. data. One of the earliest empirical studies using quarterly reports is Green and Segall (1967). They reach a negative conclusion that the first quarter earnings figure does not help forecast annual EPS figures, while Brown and Niederhoffer (1968) find the contrary.[41] Brown and Kennely (1972) use another Ball and Brown methodology and find that advanced knowledge of quarterly earnings can enhance abnormal returns of portfolios relative to the portfolio strategy based solely on annual earnings. This finding is further supported by Foster (1977), who finds that abnormal returns surrounding the interim report announcements are twice as large as ones obtained from annual reports. McNicholas and Manegold (1983) conduct a study using volatility estimates with a sample of 34 firms listed on the AMEX in 1961 and 1962. These firms began to publish quarterly reports according to the then new rule by the AMEX, and McNicholas and Manegold find that the variance of abnormal returns obtained from annual reports decreased upon the enactment of the new disclosure rule, and thus support the hypothesis that additional disclosure of quarterly reports helps decrease the price uncertainty surrounding announcement dates of annual earnings. On the other hand, as stated above, Mensah and Werner (2008) have shown that price volatility is higher in countries with quarterly reporting, like the U.S. and Canada, than in countries with semi-annual reporting like the U.K. and New Zealand. Also, Atiase et al. (1988) studied timeliness of financial reports and showed that it is strongly related to the size, and that a longer delay is associated

---

[41] See Kaplan (1978) for a review of initial literature in this field which investigated the information content of interim reports.

with smaller price reactions, suggesting there is a large inflow of information from other channels.[42]

For similar evidence in Japan on interim reports, in particular, semi-annual reports, Kubota et al. (2005) find that revisions of earnings forecasts by analysts are related to disclosure timing of the semi-annual financial statement, using data from 1980 through 2005. They find that abnormal returns generated by accruals information of the previous fiscal year's earning numbers get readjusted around this time period.

Thus, evidence for both the U.S. and other countries seem to suggest that a pricing impact is triggered when a new interim reporting requirement is imposed on the market. In this paper we investigate these effects from the aspect of private information trades and stock liquidity.

2.4 PIN Model Used

The details of the model originally developed by Easley et al. (1996) and extended in Easley et al. (2002) are summarized in Appendix A and we outline only the estimating equation below. In their original model there are three types of market participants: market makers, informed traders, and uninformed traders. However, based on comparable parameter estimates by Kubota and Takehara (2009a) on Tokyo Stock Exchange firms and by Atkas et al. (2003) on Paris Bourse firms to the NYSE firms by Easley et al. (2002), we directly apply the PIN estimation method to the electronic order driven market of the Tokyo Stock Exchange and investigate the relative weight of private information trades and public information trades. [43]

In their original model there are two types of traders in the market: informed traders and uninformed traders. First, nature chooses once every day whether there is a new information event with probability α, or not, with probability $(1-\alpha)$. The orders arrive according to the Poisson process and the uninformed traders send their orders with the buying order rate of ε_b and the selling order rate of ε_s. The order arrival rate by the informed is with rate μ whenever the information event arrives, and when the news is good the buy order increases at this rate and when the news is bad it decreases at this rate.

In the following equation (1) we put the symbol "hat" in the equation to denote that they are estimates from the estimating equation (A-2) in Appendix A. In estimating the

---

[42] The thorough investigation of the relationship between the PIN, liquidity, and the volatility is our future work.

[43] We thank Maureen O'Hara for discussing this point. Kubota and Takehara (2009a, p. 321) discuss why limit orders can play the role of market makers for the Tokyo Stock Exchange data. When Foucault (1999) analyzes the nature of dynamic limit order markets, he refers to the Tokyo Stock Exchange as a representative market of this kind. Moreover, Back and Baruch (2004) prove the equivalence of the floor market and the market with market makers under suitable regularity conditions.

parameter vector with tick data we numerically maximize this likelihood function without constraints using a standard computing procedure.[44]

$$PIN = \frac{\hat{\alpha}\hat{\mu}}{\hat{\alpha}\hat{\mu} + \hat{\varepsilon}_b + \hat{\varepsilon}_s} \qquad (1)$$

This PIN variable, based on Bayes's theorem, represents the *ex post* probability that the trades are triggered by private information among all tick-by-tick trades. In (1) the numerator denotes the number of orders which is composed of the information-based order arrival rate times the occurrence of the information event, and the denominator is the total sum of the information-based trade and the sell and buy trades for the non-information event case.

In estimating the necessary parameters as shown in Appendix A's equation (A-2), we use tick-by-tick records for all the stocks and classify each transaction as either a buy or a sell order without ambiguity with the following method.[45] That is, all previous and current bid and ask quotes are recorded in our dataset, and based on these quotes, we classify all transactions as either buy or sell depending on whether each market-cleared transaction is determined either above or below the middle point of the most recent bid and ask price. We impose further conditions, in that at least 45 days of trading data are available to compute the quarterly PIN for each firm.

3. Definition of the Variables Used and the PIN Estimates

The data we use for this study is as follows. First, the sample is firms listed in the first and the second section of the Tokyo Stock Exchange from 1996 through the third quarter of 2008.

To estimate the PIN variable we use tick-by-tick quote and transaction data provided by Nikkei Media Marketing Co., Ltd. For financial data, the source is again Nikkei Media Marketing Co., Ltd. Two variables we use are: lnMV, which is a natural logarithm of market value of equity (in million yen), and B/M, which is the book-to-market ratio of the firm in percent. These financial attributes of the firm, lnMV and B/M, are computed from the Nikkei Portfolio-Master Database.

As for the record of quarterly disclosure by firms listed in the Tokyo Stock Exchange, we use the "eol" on-line database provided by eol, Inc. This data is originally constructed by the TD-Net of the TSE, and the data is automatically transmitted to eol, who construct their database from HTML and PDF files of quarterly financial statements from the TSE. We conduct the content search using eol's search engine to collect necessary data.

---

[44] We estimate the parameters by using the function "min_uncon_mulvar" in the IMSL CMATH Library. This function uses a quasi-Newton method to minimize the multivariate function and the details of our algorithm as explained in Dennis and Schnabel (1983). The resulting estimates of the PIN variable belong to a class of asymptotically efficient estimators (Amemiya, 1985).

[45] Hence, we do not have to use the conventional "tick test" which is the case for markets with specialists.

Based on the collected records from eol, we construct a dummy variable called the "QDDummy" variable and this variable is assigned value 1 if we find quarterly financial statements, and it assigned value 0 otherwise. As for the number of analysts following the firm, which we call "NAnalysts," this figure is computed based on the I/B/E/S International Summary History File provided by Thomson Reuters Markets KK.

To construct the liquidity measures, we compute two alternatives: ILLIQ by Amihud (2002) and the turnover ratio. The data source is the Nikkei Portfolio-Master Database.

The definition of these measures is as follows. First, let $NSTD_{j,t}$ denote the number of shares of firm j traded in month t, and $NS_{j,t}$ denote the number of shares outstanding for firm j at the end of month t. Then the '$Turn_{j,t}$', turnover ratio of firm j in month t is defined as

$$Turn_{j,t} = NSTD_{j,t} / NS_{j,t} \qquad (2)$$

This variable measures the degree of liquidity by looking at the trading volume, which is a standard measure used in microstructure studies.

Next, the "illiquidity" measure proposed by Amihud (2002) is defined as the average ratio of the daily absolute return to the trading volume on that day. Let $D_{j,t}$ denote the number of days in which trading volume of firm j is strictly positive, $r_{j,d,t}$ denote the daily return of stock, and $v_{j,d,t}$ denote the trading volume in million yen. Then, $ILLIQ_{j,t}$, the illiquidity measure by Amihud (2002) for firm j in month t is defined as follows.

$$ILLIQ_{j,t} = \frac{1}{D_{j,t}} \sum_{d=1}^{D_{j,t}} \frac{|r_{j,d,t}|}{v_{j,d,t}} \qquad (3)$$

This measure is widely used in asset pricing theory tests in financial economics (for example, Avramov et al. (2006) for U.S. data and Kubota and Takehara (2009b) for Japanese), and we choose to use this measure.

The additional two variables that we use as control variables in our regression analysis are the number of analysts following each firm and the number of outstanding series of corporate bonds. The first variable is directly taken from the I/B/E/S data and we count the number of earnings' forecasts at the end of each quarter for each firm. The second variable is from the Nikkei NEEDS Database and the counts the number of series of outstanding bonds. These are to control for the general inflow of firm-related public information. Analysts contribute to increased information about firms' future profitability and thus, on stock returns, and the new issuance of corporate bonds needs new credit ratings each time by credit rating agencies.

Next, we report the basic PIN estimation results in Table 2, Figures 1, and Figure 2.

TABLE 2 ABOUT HERE
FIGURE 1 ABOUT HERE
FIGURE 2 ABOUT HERE

319

In Table 2 we report average values of estimated PINs for all quarters from fiscal year 1996 through 2007. First of all, we find that general tendencies for PIN values decline over time, although not uniformly. In earlier years, we find the PIN for the fourth quarter is the largest with 22.782 and 22.278 for the first quarter. The numbers for the second and third quarter are smaller at 21.617 and 20.976, respectively. In recent years after the majority of quarterly reports became publicly available to analysts and investors, however, we find that the patterns become almost indistinguishable: i.e., 15.389, 15.356, 15.225, and 15.260 for the first, second, third, and fourth quarter, respectively, in 2007. So we conjecture that quarterly disclosure has something to do with the seasonal differences of the PIN value.

The above pattern can also be easily seen from Figure 1 where each horizontal line is the overall mean of PIN values for each quarter, and the data is stacked by quarters so that one can find time-series patterns of quarterly PINs. From the figure we can clearly read the declining pattern of PIN values for each quarter.

In Figure 2, the same data are plotted in the year scale graph on which all four quarter values are stacked on the same time year scale. By comparing the former year data with the recent year, one can confirm that seasonal differences of the PIN, as read as vertical representation of each quarter's estimates, began to decrease from fiscal year 2003 and 2004. Thus, we infer that the new quarterly disclosures had something to do with the decrease in PIN values. This is in conjunction with our hypothesis *H1*. We will conduct further tests in the next section to pinpoint further the firm-wise behavior of these PIN values after controlling for firm-specific variables.

Table 3 reports PIN values as well as other firm characteristic variables by dichotomously splitting the sample into sets of quarterly report disclosing and non-disclosing firms. In each panel the second column reports the average values for disclosing firms and the third column reports the same for non-disclosing firms. The fourth column computes the mean difference and the fifth column reports corresponding *p*-values.

TABLE 3 ABOUT HERE

Note we report in Table 3 only the results for the second and fourth quarter, at which time quarterly earnings reports for the previous first and third quarter are formally reported. Note that the second and fourth quarter correspond to the periods when either the fiscal year-end financial statements or the semi-annual financial statements are still computed in-house and then published in the succeeding first and third quarter, respectively. The quarterly report for the second and fourth quarter which are to be reported in the third and the first quarter are thus nothing but the subset of the semi-annual and fiscal year full financial statement. This is why we do not report the results for these two quarters, as we are only interested in investigating the impact of new quarterly interim reporting, which did not exist in earlier years for Japan.

In Panel A of Table 3 we find that unanimously disclosing firms have higher average PIN values than non-disclosing firms for all quarters in fiscal year 2003 to 2007. For the fourth quarter of 2007, for example, the numbers are 0.148 vs. 0.166 and the difference

is -0.017 with *p*-value 0.000. Except for three cases, the differences are significant. That is, there is a clear-cut difference in degrees of private information-based trades in their quarterly reports between disclosing and non-disclosing firms. We find more cases of insignificant results in earlier years of the sample, and after the second quarter of 2002 they become unanimously significant and *p*-values become zero. We believe it is a very strong result that supports the possible impact of the new quarterly reporting requirement to private information-based trades.

In Panel B we report the corresponding "illiquidity" measures by Amihud (2002) and again the signs are uniformly negative, suggesting that disclosing firms are more liquid. In the fourth quarter of 2007 the numbers are 0.270 vs. 0.431. Again, except for four cases, the differences are significant at a 5% level. Particularly, it is notable that illiquidity differences between the two groups are strongly significant in all of the fourth quarters of four years of our sampling period. This is not necessarily the case with the former PIN case (Panel A) and it shows that these two variables may be related, but may contain different information. Note the fourth quarter case is from January to March in Japan when the fiscal year-end is approaching and news is flowing to the media regarding annual performance of firms, which may affect trading volume as well as stock liquidity.

Panel C and Panel D report firm characteristics of disclosing and non-disclosing firms. The size matters (Atiase et al., 1988), and disclosing firms are larger than non-disclosing firms, and the differences are all strongly significant with *p*-values zero. For the fourth quarter of 2007 the numbers are 10.695 vs. 10.248. Although disclosing firms have higher book-to-market ratios than non-disclosing firms (for the fourth quarter of 2007, 123.670 vs. 115.218) the differences are not significant in four cases out of ten, and we do not particularly conclude here.

Panel E reports the average number of analysts who follow firms measured in the final month of each quarter, and again, disclosing firms get more analyst attention (for the fourth quarter of 2007, 3.090 people vs. 1.925 people), and most importantly, the differences are significant for all quarters.

Panel F reports the number of different series of corporate bonds issued, and because we find in general that disclosing firms are larger in size than non-disclosing firms, we also find that disclosing firms have more frequent issuances with credit ratings attached anew each time.

4. Empirical Results

We report our empirical results in this section. Table 4 reports the correlation coefficients of the pertinent variable which we use for the pooled OLS regression analyses. The upper right hand off-diagonal elements report Pearson correlations and the lower left hand off-diagonal elements report Spearman rank correlations. Panel A is the result for disclosing firms and Panel B is the result for non-disclosing firms.

TABLE 4 ABOUT HERE

Because some of the variables are not continuous variables, we interpret primarily the results from Spearman correlations. In Panel A we find that the PIN value is positively correlated with illiquidity at 0.484 and in Panel B we find that the same number is smaller for non-disclosing firms at 0.220. So the illiquidity of non-disclosing firms may contain other underlying economic factors other than private information-based trade. On the other hand, we find for disclosing firms the degree of private information-based trade has a stronger direct relationship with the illiquidity measure. Duarte et al. (2008) finds that the impact of Regulation FD on the cost of capital was different between NYSE firms and NASDAQ firms, using the PIN variable. We also use both the first and second section firm samples of the Tokyo Stock Exchange, and it is not a surprise that the smaller non-disclosing firms from the second section have more illiquidity problems, which do not result from private information-based trade *per se.* For example, Kubota and Takehara (2009a, Table 4) find that smaller firms have smaller information arrival rates and larger bad information arrival rates than larger firms for the first section TSE firms. Again, we will not conclude with just this correlation number between PIN and "illiquidity" and we will test this relationship in a formal multivariate analysis below.

In Table 4, for both disclosing and non-disclosing firms, the PIN value is negatively related to size, number of analysts, and amount of different series of bonds issued, which are quite intuitive, and positively related to book-to-market ratios, which means depressed firms have higher PIN values. We find the correlations are overall larger for disclosing firms and we suspect there is more room for unexplainable elements for non-disclosing firms.

A caveat here is that the clearer-cut relationship between public information and the PIN among disclosing firms may either be an indication that quarterly reporting helps, or that there is a self-selection of good firms who keep sending signals to markets and thus the financial attributes and quality of firms may be more opaque than non-disclosing firms. We cannot distinguish between these two different scenarios judging only from this correlation table and because it suffers from a typical endogeneity problem.[46]

Next, Table 5 reports the regression results, in which the dependent variable is the PIN, and regression analyses are conducted for all pooled samples and for the second and third quarters. Panel A is for all samples including all four quarters, Panel B is for the second quarter, and Panel C is for the third quarter. Note all sample cases include the time periods of both semi-annual financial statement disclosure and fiscal year-end financial statement disclosure.

TABLE 5 ABOUT HERE

As explained above, in the regression, QDDum is the dummy variable which takes value 1 if a firm discloses quarterly reports and 0 otherwise. The "illiquidity" measure we use is the Amihud (2002) measure defined in (2). The regression coefficient of QDDum,

---

[46] This is our ongoing research. First, we entangle the fixed effects and the random effects. Second, the firm's choice to disclose or not to disclose can be incorporated, for example, by Heckman's two step procedure. Finally, entangling the joint effects of the liquidity and the private information trade within a simultaneous equation framework is for our future endeavor.

which is shown in the second row of Panel A, is negative and significant, which means the intercepts are different between disclosing and non-disclosing firms. Without other controls, the intercept (unconditional predictor of PIN) is 0.182 for non-disclosing firms and 0.160 for disclosing firms. With all the control variables included, as shown in the bottom row of this panel, the intercepts are 0.325 vs. 0.309, respectively. After we add control variables, the intercept estimates increase.

Among the explanatory variables we find that the "illiquidity" measure, the number of different series of bonds issued, and book-to-market ratios are not significant for all sample cases as shown in Panel A. The number of analysts and the size are significant. The signs are as *a priori* expected and confirm the result in Table 4. The results for each quarter in Panel B and Panel C, when neither the semi-annual financial statement nor the fiscal year financial statement is published in the same quarter, show a drastically different picture of the "illiquidity" variable. This time this variable becomes strongly significant though the coefficient is in accordance with our prior information only in the second quarter. Note it is the informationally quieter interim period between the fiscal year- end and the forthcoming semi-annual report, and we find that the illiquid (liquid) stocks have higher (lower) PIN values conditional on whether or not they disclosed quarterly reports. For the fourth quarter, the sign does not match with our prior information, but in view of the large quantity of information inflows into the market as the fiscal year-end approaches, there may be more missing control variables in this regression equation. Finally, once again we find that the number of different series of bonds issued and book-to-market ratios are not significant. Overall, the evidence supports our hypothesis *H2*.

In Table 6, by reversing the order of the set of the independent and dependent variables, we try to explain the stock liquidity by using the estimated PIN and other same control variables. Because we want to explain the liquidity in this regression, we conduct two types of regressions using two measures of liquidity as defined in (2) and (3) above.

TABLE 6 ABOUT HERE

Panel A is the case for the Amihud measure and Panel B is for the turnover ratio. Thus, the signs ought to be opposite each other. In the bottom row of Panel A, for the case with all the control variables included, we find that the sign of PIN is positive as predicted, but it is not significant at 0.021 with *p*-value 0.702. However, when we do not control for the size or book-to-market ratio as shown in the upper second row from the bottom and also when we include only the PIN and disclosure dummy variable as shown in the next row above, the PIN values become larger (0.745 and 1.097, respectively). Accordingly, when we pool the sample and do not control for size and value effects, we find that the PIN value can explain significantly the directions and magnitude of the estimated Amihud illiquidity measure, and this result supports our hypothesis *H2*. Note also that the dummy variable is strongly significant and the sign is negative as predicted. As was the case of the estimates for the PIN, the absolute values of the estimated coefficients are larger for the cases without control variables than the case with control variables (-0.145 and -0.144 vs. -0.058, respectively).

323

In Panel B where we use the monthly turnover ratio as a dependent variable, the result is much stronger in the sense that even when all the control variables are included, the variables of our interest remain significant. The coefficient for the PIN (in the bottom row of Panel B) is -0.441 with *p*-value 0.000. The coefficient does not change even if the control variables drop (-0.420 and -0.397, respectively) and the result is quite robust. The case is similar for the disclosing dummy variable, in which case the coefficients are 0.018, 0.015, and 0.015 with all *p*-values at 0.000.

By summarizing these results as reported in Table 6, we conclude that the PIN variable helps explain the change in liquidity and supports our hypothesis *H*3, and the stocks of disclosing firms of quarterly reports are traded with higher liquidity than stocks of non-disclosing firms, even after controlling for differences in the probability of private information-based trades.

In sum, based on the strong support of our hypotheses *H*2 and *H*3, which says that the increase in this liquidity is brought about by the decrease of PIN over time, we infer that it is highly likely that these phenomena were triggered by the introduction of the new quarterly reporting requirements issued by the Tokyo Stock Exchange. In conclusion, our findings are in accordance with our first hypothesis *H*1, which claims that the new disclosure regulation can decrease the probability of private information-based trades.

5. Conclusion

We investigate whether quarterly disclosure reporting requirements issued by the Tokyo Stock Exchange on April 1, 2004, the related Financial Instruments and Exchange Act of Japan, and the new quarterly accounting standards helped reduce the degree of private information-based trade for listed stocks, utilizing the PIN variable proposed by Easley et al. (1996, 2002). We find that it is indeed the case and that there are significant differences between firms which issued quarterly reports by abiding by the exchange rule and firms which did not. We find that such a difference is strongly related to the differences in the estimated liquidity measures of these stocks. Our paper can shed light on the distribution of private information in the Japanese stock market after the disclosure rule was introduced, which is a new finding.

Appendix A: On the PIN Model

It is assumed that there is a sequence of trades which is repeated over *I* (*i* = 1, 2,…, *I*) trading days. In this model it is assumed that there are two types of traders in the market, informed traders and uninformed traders. Initially, nature chooses once every day whether there is a new information event with probability α, or not, with probability $(1-\alpha)$. Given that new information arrives in the market, it initially gets revealed only to informed traders. If it is good news, the firm value is assessed to be V_i^H and, if it is not, it becomes V_i^L ($V_i^L < V_i^H$). The probability of good news is denoted as $(1-\delta)$ and the probability of bad news is denoted as δ. In the original

model by Easley et al. (1996) the risk neutral market maker will act as an intermediary, and via her/his profit maximizing behavior of sending her/his ask and bid quotes into the market, the equilibrium price eventually obtains.

The traders' arrival process is as follows. It is assumed that traders arrive at the market according to continuous time Poisson process at every minute of trading in the model. Note that, depending on whether or not new information has arrived, informed traders may or may not get into the market. Orders from informed traders arrive at the rate μ, with a Poisson process, given that the information event has occurred. On the other hand, the buy order arrival rate and the sell order rate from uninformed traders are also drawing from a continuous Poisson process and the former is denoted as ε_b and the latter as ε_s.

Then, the estimating model is as follows. On every day of trading the likelihood of observing the quantity of limit buy orders *B* and the quantity of sell orders *S* are computed as in the next equation (A-1). In (A-1) the first term is the case of a no information event, the second is the case of a bad news event, and the third is a good news event. The indicator variable Ψ in (A-1) takes a value of either one of –1, 0, or 1, which specifies which of the above three events have taken place. The vector of the parameters is denoted as $\theta = (\alpha, \mu, \varepsilon_b, \varepsilon_s, \delta)$.

$$L(\theta|B, S, \Psi) = L(\theta|B, S, \Psi = -1) + L(\theta \,|\, B, S, \Psi = 0) + L(\theta \,|\, B, S, \Psi = 1)$$

$$= (1-\alpha)e^{-\varepsilon_b} \frac{\varepsilon_b^{B}}{B!} e^{-\varepsilon_s} \frac{\varepsilon_s^{S}}{S!} + \alpha\delta e^{-\varepsilon_b} \frac{\varepsilon_b^{B}}{B!} e^{-(\mu+\varepsilon_s)} \frac{(\mu+\varepsilon_s)^{S}}{S!} \qquad \text{(A-1)}$$

$$+ \alpha(1-\delta)e^{-(\mu+\varepsilon_b)} \frac{(\mu+\varepsilon_b)^{B}}{B!} e^{-\varepsilon_s} \frac{\varepsilon_s^{S}}{S!}$$

As every trading day is assumed to be an independent drawing in the model, the likelihood function for observing the data $M = \{B_i, S_i\}_{i=1}^{I}$ after the elapse of *I* days can be simply written as the product of each daily likelihood function (A-1).

$$L(M \,|\, \theta) = \prod_{i=1}^{I} L(\theta|B_i, S_i, \Psi_i) \qquad \text{(A-2)}$$

Using sample observations, we estimate the likelihood function (A-2) and obtain the estimates of the information-based trade PIN variable defined in equation (1) of the main text by Bayes' rule.

Appendix B: On the Duarte and Young (2009) Estimation Method

As an extension of this research, we also estimated the stochastic process proposed by Duarte and Young (2009), in which the additional systematic order flow shock governed by the extra Poisson arrival is added to the original arrival process in Easley et al. (1996, 2002). Because this new estimation method is yet well established relative to the conventional PIN estimation method, we decide to report the summary result of this method in the Appendix.

First of all, during the estimation process, unlike in the conventional PIN estimation, we find that estimated alphas hit the lower bound often (17.13% of the sample) and the deltas hit the upper bound more often (39.08%). Moreover, we frequently had to reiterate computations by plugging in alternative initial values by generating random numbers so that the global maximum could be finally reached. We infer that these apparent shortcomings come from the more complex stochastic processes assumed. We judge these estimation problems may blur the original implications from Easley and O'Hara's PIN model, about which we already know the robustness of estimates.

Besides, as far as we compare the estimated results of the conventional PIN and the Duarte and Young method for our sample, we also cast some doubt about the obtained estimates.

Below is the summary of our estimation results.

TABLE A-1 ABOUT HERE

Panel A reports the average values of the estimated PIN variable using Duarte and Young's (2009) three stage information arrival process, and we find that the estimated PIN values are almost half of the conventional PIN values. This is not a problem *per se* if the remaining probability mass is impounded into the probability of the systematic order-flow shock that Duarte and Young (2009) introduce. However, the time-series pattern of PIN estimates shown in the table reveal that the PIN value becomes larger as time elapses and *vice versa* for the probability of the systematic order flow. Considering that the trading volume remained stale after the crush of the 1989 bubble and the 2000 IT-related bubble for the Japanese market, the latter result for the systematic order flow looks odd to us.

As we discussed in the main text of the paper, the PIN estimates are the focus of the paper. However, in Table A-1 we find that the probability of private information-based trade increases as the years pass. This phenomenon does not look convincing because we know that there was drastic advancement in disclosure rules and related stock market regulations in Japan, including the rapid convergence efforts of accounting standards to the International Accounting Standards by 2015, the new Corporate Law of 2006, and the Financial Products and Services Law of 2007, the last one resembling the U.S. Sarbanes-Oxley Act. Thus, we do not think our estimated result using the Duarte and Young (2009) method can well explain the probability of private information-based trade. Thus, in the main text of the paper we decide to use only the conventional PIN estimates whose robustness is better known across world markets.

FY2006Q3	2,114	73.746	1745	74.785	369	68.835
FY2007Q1	2,082	74.784	1738	75.662	344	70.349
FY2007Q3	2,032	75.640	1735	76.542	297	70.370

Table 2. The Quarterly Pattern of PIN

The average value of the estimated PIN is reported for each quarter and for each year of our sampling period. The samples are all the firms listed in the first section and the second section of the Tokyo Stock Exchange and the results for each first and third fiscal quarter of the year are reported. The first quarter starts April 1 in Japan. The maximum number of firm observations is 2,127 for the second quarter of 2003 and the minimum is 1,282 for the first quarter of 1998.

	Q1(Apr-Jun)	Q2(Jul-Sep)	Q3(Oct-Dec)	Q4(Jan-Mar)
1996	22.278	21.617	20.976	22.782
1997	22.097	20.517	21.884	23.119
1998	22.801	21.965	22.227	23.375
1999	20.944	19.750	18.367	18.326
2000	18.879	19.492	17.852	20.634
2001	19.546	18.832	19.121	20.523
2002	19.837	21.223	18.996	18.966
2003	18.183	17.183	17.376	18.677
2004	17.857	16.967	17.153	16.905
2005	16.680	15.718	15.126	15.652
2006	15.369	15.750	15.825	15.793
2007	15.389	15.356	15.225	15.260

Table 3. Characteristics of the Sample Firms

The characteristics of sample firms are reported for each quarter and each month. For each panel, the average of firms who disclosed the quarterly reports, the average of firms who did not, the mean difference, and the *p*-value for Wilcoxian mean tests are reported. Panel A reports PIN, Panel B reports the illiquidity measure by Amihud (2002), Panel C reports the market value of the firms, Panel D reports the book-to-market ratios, Panel E reports the average number of analyts' followings during the last month of each quarter and Panel F reports the number of outstanding brands of corporate bonds for the same month as above. Note the first quarter starts April 1 in Japan.

Table 5. Results of Regression Analysis

The dependent variable, PIN, is the measure of private information-based trade defined in Easley et al. (2002). Panel A is for all the quarters, B is for the second quarter, and the C is for the third quarter. QDDum is a dummy variable which equals one if the firm disclosed quarterly financial statements. ILLIQ is the illiquidity of the firm defined in Amihud (2002). NAnalyst is the number of financial analysts who follow the firm. lnMV is a natural logarithm of the firm's market value of equity in million yen. B/M is the book-to-market ratio in percent.

1.5 Corporate Governance

AGENCY THEORY AND MANAGERIAL OWNERSHIP: EVIDENCE FROM MALAYSIA

Mazlina Mustapha, Faculty of Economics and Management, Universiti Putra Malaysia, Assoc Prof Dr Ayoib Che Ahmad, College of Business, Universiti Utara Malaysia

Abstract

This paper tests the effect of managerial ownership in relation to agency theory in Malaysian business environment. Besides examining the total managerial shareholdings, this study also examine the association between direct and indirect managerial shareholdings with agency costs. The results of the study indicate that managerial ownership in various segments has inverse relationship with total monitoring costs as predicted in agency theory. This finding is consistent with earlier studies in western countries and supports the convergence of interest hypothesis. This result may be explained by the fact that as the managers are also the owners, there is less conflict, less information asymmetry and less hierarchical organisation structure in the companies, which lead to lower monitoring costs.

Keywords: *ownership structure, managerial ownership, agency theory, monitoring costs.*

1.0   Introduction

The separation of ownership and management functions may lead to the possibility of principal–agent conflicts as the managers may not always act in the shareholders best interests and may misuse the corporate assets (Jensen & Meckling, 1976; Shleifer & Vishny, 1986). This divergence of interest between managers and shareholders may lead to"agency problems", and results in agency costs as described in agency theory (Farrer & Ramsay, 1998). Various factors have been considered to overcome this problem and reduce the costs. Among others is the convergence of interest model suggested by Jensen & Meckling. This model posits that as the agency costs arise as a result of the separation of ownership and control, this cost would be zero if those who owned the company also managed the company (Farrer & Ramsay, 1998). This can be

done by encouraging the managers to own the company's shares, as the interest of the internal and external shareholders are aligned.

When managers own the shares of the firm, they have the incentive to increase the value of the firm rather than shrink as they have entrepreneurial gain in the company (Jensen & Meckling, 1976). It is believed that incentive to consume perquisites declines as manager's share ownership increases because his share of firm's profit increase with ownership while his benefits from perquisite consumptions are constant (Ang, Cole & Wuh Lin, 2000; Fleming, Heaney & McCosker, 2005), and accordingly, the incentive to pursue personal benefits increases when he own smaller portion of the firm's shares (Mat Nor & Sulong, 2007). Furthermore, as the owners are actively engaged in day to day activities of the company (Nimie, 2005), there will be less information asymmetry, less conflicts and less hierarchical organisation structure. This less complex organisation structure reduces the need for assurance and monitoring, thus require less monitoring and agency costs.

Besides that agency theory is also criticised for its ignorance of the existence of social and authority relationship and assumes social life is a series of contract (Johnson & Droege, 2004). It is unknown whether the agency theory findings in western countries have equal impact in Asian organisations (Ekanayake, 2004; Johnson & Droege, 2004). Previous literatures (Conlon & Parks, 1990; HassabElnaby & Mosebach, 2005; Ekanayake, 2004) indicate that there is a possibility that given the cultural differences, the typical nature of agents in agency theory may not be the case with regard to non-western countries. Sharp & Salter (1997) argue that the agency effects are lower in Asia. It is also claimed that there is a limited empirical research that directly tests agency theory in different culture context (Ekanayake, 2004).

337

Thus, this study empirically examines the agency relationship in Malaysian organizations, one of the countries in Asia. Besides being a developing country with an emerging market, Malaysia is chosen in this study because of its unique concentrated business environment. It is claimed that owner managed firms are common among Malaysian companies (Mat Nor & Sulong, 2007).Unlike companies with dispersed shareholdings, these companies are believed to have reduced agency problem and agency costs due to a better match of control and cash flow rights of the shareholders (Abdul Rahman & Mohamed Ali, 2006). Specifically this study focuses on the effect of managerial ownership on the agency costs of Malaysian public listed companies. This study uses the direct measure of agency costs, which are the cost of monitoring the companies as recommended by Malaysian Code of Corporate Governance (FCCG, 2001). This study aims to provide evidence that support or reject prior research findings in western countries relating to the effect of managerial ownership on the agency relationship which is reflected in its agency costs.

This study investigates various ownership shareholdings, which include direct, indirect and total managerial shareholdings and their effect on monitoring costs. The results indicate negative relationship for all categories of ownership, which is consistent with prior studies in western countries. This is supported by the independent t-test which indicates that those companies having managerial ownership in their organizations have significantly lower monitoring costs compared to those without such holdings. Another t-test for those companies with low and high managerial ownership also gives similar result. The analysis relating to the board of directors' shareholdings and monitoring costs also show the same pattern of result.

The remainder of the paper is organised as follows. The next section discusses the relevant literature on the role played by managerial ownership in agency setting and how it affects the agency costs. The methodology employed in this study is outlined in Section 3 and the results of empirical testing are presented in Section 4. The paper ends with the conclusion of the research.

2.0   Literature review

Principal-agent relationship in agency theory

Initially, physical assets defined an individual's net worth to denominate wealth (Carlson, Valdes & Anson, 2004). Examples of such assets are lands. Kings and members or royalty defined their power based on the land that they owned. Later, as the economic activities changed from agricultural to industrial economy, this basis changed from ownership of land to ownership of legal entities. In their discussion of the origin of the word "share ownership", Carlson et al. further claim that as a consequence of industrial revolution, public organisations are established to create goods and services and stocks and bonds are created to support the financing of the new enterprises. These stocks also reflect the ownership of the organisations. If in the past, banks are the custodians of physical assets of their clients (such as coins, jewels, and land deeds), with the full force of industrial revolution, banks begin to "hold shares of ownership" in public organisations, which create the term "shareholders".

With the acceptance of industrial revolutions also, organisations grow bigger, and the owners are no longer the managers of the organizations. It is not practical for the shareholders to make day to day decisions of the organizations and this job is delegated

to the managers. This separation between the owner and managers tends to create agency problems as claim in agency theory.

Agency theory postulates that the firm consists of a contract between the owners of economic resources (the principal) and management (the agents) who is charged with using and controlling these resources (Jensen & Meckling, 1976). The agency relationship between the principal and the agent give rise to agency costs because the managers may not act in the owners' best interest, such as consumption of excessive perquisites and sub-optimal investments (Fleming et al., 2005). Agents normally have more information than principals and this information asymmetry adversely affect the principal's ability to monitor whether their interest are being properly served by the agents (Adams, 1994). The principals want to ensure that their resources are being utilized in the best manner possible, which later will flow back to them in the form of dividend. Whereas the agents are also concern as this would be the measurement of their efficiency in managing the company, and may be the source for the determination of their salary/remuneration in the future.

In the process of discharging the duties, agency theory assumes that the agents and principal will act rationally and they will use the contracting process to maximize their wealth. According to Kren & Kerr (1993), to ensure the efficiency in the contracting process, both principal and agents will incur contracting cost. For instance, to minimize the risk of shirking by agents, the principal will appoint the board of directors (Fama & Jensen, 1983a) and auditors. The board of directors will ensure that the management acts on behalf of shareholders, i.e. increase the wealth of the corporation (Iskandar & Mohd Salleh, 2004). An effective board of directors will provide a measure of reducing the agency problem, which will then lead to transparency of financial reporting and good

governance of the organisation. And, the external auditors will examine the financial statements prepared by the management to ensure their compliance to the standards, rules and regulations required and reflect the true and fair view of the organisation's transactions. Agents on the other hand will incur bonding cost, for example, the cost of internal audit in order to signal to the owner that they are acting responsibly and consistent with their contract of employment (Adams, 1994).

Agency costs and managerial ownership

Prior literature suggests various ways to overcome this agency problem. Among others, it is claimed that managerial shareholdings can reduce and mitigate agency costs (Jensen & Meckling, 1976; Agrawal & Knoeber, 1996; Ang et al., 2000; Chow, 1982; Fleming et al., 2005; O'Sullivan, 2000). They argued that the agency costs of equity arise from the direct expropriation of funds by the managers, consumption of excessive perquisites, shirking, sub-optimal investment and entrenching activities. Thus, earlier studies suggest that managers are encouraged to own the organisations' share to motivate management monitoring (Agrawal & Knoeber, 1996; Fleming et al., 2005). This is because the higher the portion of the stocks, the more responsible is the manager to increase the value of the companies. According to the original agency theory by Jensen & Meckling (1976), and Fleming et al. (2005), equity agency cost is zero when there is a 100% owned manager organisation, and there is a positive relationship between equity agency costs and the separation of ownership and control. As owner manager equity ownership falls below 100%, the equity ownership becomes relatively dispersed. In this circumstance, the manager has a greater incentive for shrinking or the consumption of excessive perquisites. This is due to the fact that although the firm's value falls, the managers only bear a portion of the expense related to their ownership stake (Farrer & Ramsay, 1998). In other words, a lower managerial equity holding is associated with

341

lower incentive and effort exert by the managers in their responsibilities to seek profitable investments. Chow (1982) suggest that when managers own smaller equity stake in their firms they have an increased incentive to falsify financial disclosures, since such disclosures are likely to be utilised by shareholders in setting managers' remuneration.

The incentive to consume perquisites declines as his ownership share rises, because his share of the firm's profits rises with ownership while his benefits from perquisite consumption are constant. It is also suggested that managerial shareholdings help align the interests of shareholders and managers in its convergence of interest hypothesis (Jensen, 1993).

The higher the ownership of the firm by the management, the less the conflicts among the stakeholders, the less the agency problem and cost associated with it (Friend & Lang, 1986; Jensen & Meckling, 1976). This is because the insiders have incentives to protect shareholders interests and need less supervision by the board, since board activity is a costly monitoring alternative (Vafeas, 1999). It is also said that increased agent ownership reduces the need for monitoring as the incentive alignment is enhanced. The convergence of interest model suggested by Jensen & Meckling (1976) claim that an increase in the proportion of firm's equity owned by insiders is expected to increase firm value as the interest of inside and external shareholders are realigned, and consequently there is a reduced need for intensive audit. O' Sullivan (2000) finds that significant managerial ownership results in a reduced need for intensive auditing which may be due to the merging functions of ownership and management, and consequently minimize the monitoring motivation for audit. The auditors are also said to be less inclined to undertake additional testing when managers are also significant equity

holders, since owner managers are less likely to deliberately mislead themselves (O'Sullivan, 2000). Publicly traded firms in which top management has a larger ownership stake experience corporate crime (proxy for agency cost) less frequently (Alexander & Cohen, 1999). Managers also will have more powerful incentives to make value maximising decision about capital structure as their stock ownership is high (Berger, Ofek, & Yermack, 1997). Besides increase incentive to maximise the firm value, holding common stocks also motivate the managers for its underlying voting rights, such as increase their influence on board of directors and hence on the firm's general policy (DeAngelo & DeAngelo, 1985).

However there are also studies which suggest contradict and mix findings, such as Singh & Davidson (2003) who conclude that managerial ownership does not serve as a significant deterrent to excessive discretionary expenses which is used as a proxy for agency cost in their study.

In terms of this ownership structure's association with another monitoring mechanism, that is auditing, it is found that the lower the managerial share ownership in a company, the greater the probability of the company being audited (Tauringana & Clarke, 2000). Another literature claims that agency theory suggests that in the absence of regulation, the propensity of firms to demand independent audit is a function of the extent of the divorce between ownership and control (Chan, Ezzamel, & Gwilliam, 1993). This is supported by Fan & Wong (2005) who claim that external auditors play a monitoring and bonding role in order to mitigate the agency conflict between the controlling owners and the outside investors.

It is also believed that in a manager owned organisation, managers may be excessively risk averse (Fama & Jensen, 1983b), which may lead to their under-investment in risky

343

projects, or induce managers to pursue "safe" strategies (Loh & Venkatraman, 1993). Francis & Wilson (1988) state that where the agency setting has low conflict among contracting parties (such as a manager owned organisation), a lower quality and less costly minimum compliance audits might be demanded from accounting firms with lower reputation for independence and competence. However, in the absence of manager ownership, owners tend to discount the value of their initial investment and lower the management compensation. Managers then have an incentive to choose a higher quality audit as a means of increasing their compensation (Jensen & Meckling, 1976). This is supported by Firth & Smith (1992) who find that the lower the percentage share of ownership that the management have in the company, the greater the demand for Big Eight auditor (high quality auditor).

Consistently, diffusion of ownership increases the cost and effort to affect management policy and to force a change in management. Francis & Wilson (1988) suggest that higher quality audit can be considered as part of the control system that mitigates the relative inability of diffused ownership to directly control management action.

3.0   Data and Methodology

Data and sample

Data for the study was collected using primary and secondary sources. Primary data was collected using cross-sectional surveys which were sent to Malaysian public listed companies. Data collection cannot be done solely by using secondary data, as some of the information needed (such as internal audit costs) for the study is not available from secondary sources (such as annual reports).

The population of the study includes all companies listed on the Main and Second Board of Bursa Malaysia. However, the companies classified under finance sector were excluded in this study because of their unique features and business activities, as well as differences in compliance and regulatory requirements (Yatim, Kent & Clarkson, 2006; Mat Nor & Sulong, 2007)**.** Questionnaires were sent to all 867 companies in the population as at 31 December 2006.

This questionnaire solicits information about the organisation specifically for the financial year ended 2006. Once the questionnaires were returned, the annual reports of those companies with completed questionnaires were scrutinized for further information to be used in the study. The secondary data was hand-collected from the companies' annual reports which were available at Bursa Malaysia's website (http://www.bursamalaysia.com.my).

In the annual report, the Directors' Report, Statement on Internal Control, Corporate Governance Statement, directors' profile, Shareholdings Statistics, Corporate Information, Statement of Directors' Shareholdings, the financial statements and notes to the accounts are scrutinized. Information on directors' shareholding and directors' background can be gathered from the directors' profile, Corporate Governance Statements, Shareholdings Statistics and notes to the accounts. The external audit fees, book value of the assets, total receivables, total inventories, total long term debts and number of subsidiaries can be gathered from the financial statements and notes to the accounts. The information about the existence of the internal audit department is normally included in the Statement of Internal Control; however, it is not mandatory to disclose the internal audit cost. Only 3 companies voluntarily disclose their internal audit costs. Information needed to calculate Tobin's Q and return to total assets (ROA) can be

345

gathered from the financial statements. Data from the annual reports were then transferred to the worksheets.

The information gathered from the questionnaires was also tabulated in the worksheet and further matched and validated with the information obtained from the annual report. This will then address the reliability concern of our survey data as conducted by Anderson, Francis & Stokes (1993) in their study of Australian companies. Non response bias was also conducted for the data collected from the questionnaires.

After considering the incomplete and inconsistence questionnaires, there were 235 usable samples for the study. The data was also inspected for outliers by means of standard regression diagnostics at three standard deviations (as suggested by Hair, Anderson, Tatham & Black, 1998, p. 65). Normality check of the data was also carried out and some of the measures were transformed into logarithm to control for skewed nature of data. As multivariate regression is used to analyse the data in this study, assumptions of multicollinearity, hemoscedasticity and linearity are also tested.

Variable definition

Dependent variable in this study is the monitoring costs of the companies in Malaysian listed companies. Earlier studies use indirect measurement such as asset utilization ratio (Singh & Davidson, 2003), ratio of selling and administration expenses to sales (Singh & Davidson, 2003) and ratio of operating expenses to sales (Ang et al., 2000) as proxies for agency cost incurred by the firms in monitoring their firms. But this study uses measurements that are directly related to these firms in monitoring the shareholders wealth of their companies. Directorship and auditing (internal and external) are specified as monitoring mechanisms in the Code (FCCG, 2001). Thus, the dependent variables in

346

this study involve the costs of these monitoring mechanisms demanded by the organisation in Ringgit Malaysia (RM). However, as the executive directors are in-charged of managing the companies, and the non-executive directors are said to monitor and controlling the opportunistic behaviour of the management (Jensen & Meckling, 1976; Haniffa & Hudaib, 2006), this study does not include executive directors' remuneration as monitoring costs. Hence, total Monitoring (MONITOR) is measured by the sum of organisation investment in non-executive directors' remunerations (DIRREMNED), internal auditors' costs (INTCOST) and external auditors' costs (EXTCOST).

The independent variable in this study is managerial ownership. Three measurements of managerial ownership are used. The main analysis defines managerial ownership as the total percentage of executive directors' shareholding. In order to get a clear picture of the ownership characteristics of Malaysian companies, this study also examine the effect of direct and indirect managerial shareholdings. The analysis was re-estimated by re-defined this variable into percentage of executive directors' direct shareholding only and percentage of executive directors' indirect shareholding only. The controlled variables include in the study are size, complexity, debt structure, performance, risk, growth, listing status and industry.

The following model is used to analyze the relationship between the monitoring costs and managerial ownership:

$$\text{MONITOR} = \alpha_i - b_1\text{MGROWN}_i + b_2\text{RECINV} + b_3\text{COMPLEX}_i + b_4\text{SIZE}_i - b_5\text{DEBTSTRC} - b_6\text{RISK}_i - b_7\text{ROA}_i + b_8\text{GROWTH}_i + b_9\text{LISTSTAT}_i + b_{10}\text{CONSTRASE}_i + b_{11}\text{INDPROP}_i + \varepsilon_i$$

Where:
MONITOR = natural logarithm of total monitoring costs which are the sum of external audit costs, internal audit costs and non-executive directors remuneration

347

α	=Intercept	
MGROWN	=Percentage of executive directors' shareholdings	
RECINV	=(Inventories and Receivables)/ Total assets	
COMPLEX	=natural logarithm of no of subsidiaries (including its head-office)	
SIZE	=natural logarithm of total assets	
DEBTSTRC	=Long term debt / Market value of the firm	
RISK	=1 if have loss in current year, and 0 otherwise;	
ROA	=Profit before interest and tax / Total Assets	
GROWTH	=Market value of the firm / total assets	
LISTSTAT	=1 if listed in the main board, and 0 otherwise;	
CONSTRASE	=1 if the company is in consumer, trading or services sector, and 0 otherwise;	
INDPROP	=1 if the company is in industrial, construction or property sector, and 0 otherwise;	
ε_i	= error term	

4.0   Results and discussions

Descriptive statistics

Panel A and Panel B of Table 1 presents the descriptive statistics for the variables used in the study. Panel A reports those for continuous variables and Panel B presents those for dichotomous variables.

Table 1 : Descriptive statistics of variables

INTCOST = Total internal audit cost in RM; EXTCOST = Total external audit costs in RM; NEDREMM = Total NED remunerations in RM; MONITOR = Total monitoring costs in RM; MGROWN = Executive directors' shareholdings (%);DEBTSTRC = Long term debt to market value of the firm; RECINV = Ratio of inventories and receivables to total assets; COMPLEX = number of subsidiaries(including the head office); SIZE = Total assets in RM; ROA = ROA; GROWTH = Tobin's Q; RISK = Current year loss(Dummy); LISTSTAT = Board listing (Dummy); CONSTRASE = Companies in consumer, trading and service sectors (Dummy); INDPROP = Companies in industrial, constructions and property sectors (Dummy).

Panel A shows that non-executive directors' remunerations constitute the largest component of monitoring costs, followed by internal audit costs and external audit costs ranking second and third respectively. The mean percentage of shareholdings by the managers is about 27%, which is approximate the 34% average of Haniffa & Hudaib (2006) findings using Malaysian data. The ratio of long term debt to the market value ranges from 0% to 93% with the average close to 15%. The descriptive statistics also show that the sample companies cover a wide range of companies, some moderately small and some relatively large, range from those with RM18 millions to RM65,092 millions of total assets. The complexity of the companies in terms of their operations range from simple, where there are companies with only their head office with no subsidiary, to more complex. The complexity of their assets' compositions also reflect the same pattern, the ratio of inventories and receivables to total assets range from 0.19% to 80% and the average is about 31%. On average, the respondent companies have the total assets of RM1,564 millions and 20 subsidiaries, while the average Tobins' Q is approximately 1.05. Panel B reports that about 75% of the companies are listed in the main board of the Bursa Malaysia, and the balance in the second board. Only 20% of the companies suffer a loss in the current year.

Variable definition:

MONIITOR = Total monitoring costs(ln); MGROWN = Executive directors' shareholdings (%); DEBTSTRC = Long term debt to market value of the firm; SIZE = Total assets(ln); COMPLEX = number of subsidiaries(ln); RECINV = Ratio of inventories and receivables to total assets; ROA = ROA; RISK = Current year loss(Dummy); GROWTH = Tobin's Q; LISTSTAT = Board listing (Dummy); CONSTRASE = Companies in consumer, trading and service sectors; INDPROP = Companies in industrial, constructions and property sectors.

The results of standard tests on skewness and kurtosis in Table 2 indicate that there is no problem with normality assumption[47]. A visual check for normality using histogram and normal probability plots is also carried out. All the histograms appear to be reasonably normally distributed and the normal distribution of the probability plot forms a straight line and the values appeared to fall approximately on this normality line. Thus, these variables can reasonably be considered as normally distributed. In summary, the model does not violate the basic OLS assumptions and could be used to test the expected hypotheses.

---

[47] The data is said to be normal if the standard skewness is within ±1.96 and standard kurtosis is between ±3.0 (Mat Nor & Sulong, 2007; Abdul Rahman & Mohamed Ali, 2006; Haniffa & Hudaib, 2006).

Table 3 presents the correlation matrix for the dependent and independent variables. The result indicates that there is no multicollinearity problem, as the correlations are below the threshold value of 0.8 (Gujarati, 2003, p. 359).

(i) Main results

Column two of Table 4 presents the multiple regression analysis used to test the main model. The adjusted R squared for the model is 0.753 and the F-value of 66.022 is significant (p< 0.000). The value of the adjusted R square is very high, as well as statistically significant, which suggests that it is a good predictive model of monitoring costs for Malaysian data. It means more than 75% of the variation in the monitoring costs can be explained by the model. This adjusted R squared is also very much higher compared to a similar study by Anderson et al. (1993) on monitoring cost, which use Australian data, but with only one independent variable (assets in place), where its adjusted R-squared is 0.423.

The independent variable, managerial ownership appears to have significantly negative relationship with monitoring costs as predicted by agency theory. This result implies that the greater the managerial ownership in an organisation the lower is its total monitoring costs. This finding is consistent with earlier studies in western countries by Jensen & Meckling (1976), Fleming et al. (2005), Ang et al. (2000), Jensen (1993), Nimie (2005) and Friend & Lang (1986).

This result is also consistent with the convergence of interest model which claim that an increase in the proportion of firm's equity owned by insiders is expected to increase firm value as the interest of inside and external shareholders are realigned, thus result in less conflict among the shareholders. Furthermore there will be less information asymmetry and less hierarchical organisational structure as the managers are now the owners, and are actively engaged in day to day activities of the organisations (Nimie. 2005). This is

agreed by Ang et al. (2000) and Fleming et al. (2005) who claim that the managers' incentive to consume perquisites declines as their ownership share rises because his share of the firm's profits rises with ownership while his benefits from perquisite consumption are constant. A local study by Mat Nor & Sulong (2007) also argues along the same line by claiming that when managers own a smaller portion of the organisation's share, they have greater incentive to pursue personal benefits and less incentive to maximise firm values. In addition, holding common stocks also motivate the managers for its underlying voting rights, such as increase their influence on board of directors and hence on the firm's general policy (DeAngelo & DeAngelo, 1985).

Furthermore, this result may also be more pronounced in Malaysian concentrated business environment, where owner-managed companies are common among listed companies in Malaysia (Mat Nor & Sulong, 2007), especially with family businesses (as claimed by Haniffa & Hudaib, 2006). This concentrated agency setting is expected to have low conflict among the contracting parties (Fleming et al., 2005; Fama & Jensen, 1983a), thus lead to low risk (Francis & Wilson, 1988) and low monitoring costs. They tend to run the businesses themselves or appoint family members, and they are concerned with the survival of the organisations, not only over their lifetime, but also with the well-being of the next generations (Bhattacharya & Ravikumar, 2001). Thus, they will really consider the monitoring costs incurred by the companies and the allocation of the resources in order to ensure the future survival of the organisations.

(See variable definition in Table 2)

The finding of this study is also consistent with a study by Nikkinen & Sahlstrom (2004) who conduct an analysis of audit pricing (one of the monitoring costs in this study) and its relationship with agency theory by using data from seven countries including Malaysia. Consistent with the theory, they find a significant negative relationship of managerial ownership with audit fees at 5% level of confidence for Malaysian data.

(ii) Further tests

In order to get a clear picture of the ownership characteristics of Malaysian companies, sensitivity analysis are also carried out. The proxy for managerial ownership (MGROWN) is defined as the percentage of executive directors' total shareholdings. As a test of sensitivity, the main model is re-estimated with the independent variable MGROWN redefined as the percentage of executive directors' direct shareholdings only. The result for the model is not affected by this alternative. As expected in agency theory, the result in column three of Table 4 appears to suggest that the greater the direct managerial control in the organisation, the lower is the relative expenditure in total monitoring.

Another test of sensitivity is conducted where MGROWN is redefined as the percentage of executive directors' indirect shareholdings only. Again, the result for the model is not affected by this alternative. As expected in agency theory, the result indicates that indirect managerial control in the organization has an inverse relationship with total monitoring costs (refer column four of Table 4).

Alternatively, the proxy for managerial ownership (MGROWN) is redefined as the percentage of board of directors' total shareholdings which includes both executive and non-executive directors' shareholdings. The result for the model

in column five of Table 4 is not affected by this alternative. The result suggests that the greater the managerial control (by both executive and non-executive directors) in the organization, the lower is the relative expenditure in total monitoring costs in directorship and auditing. The direction of the relationship is as predicted in agency theory.

Further tests in column six and seven of Table 4 are carried out by segmenting the sample companies into (a) companies with high and low managerial shareholdings by using the average managerial shareholdings in Table 1 as a cut-off point; and (b) those companies which have managerial shareholdings and those with no managerial shareholding. The main model is re-estimated using these alternatives. The re-estimated results for both alternatives indicate that managerial ownership has negatively significant relationship with monitoring costs at $p < 0.01$, while other variables remain the same.

Independent t-tests are also carried out using the same segmented data in (a) and (b). Both test results show significant results. The result of the test reveals that the monitoring costs of companies which have high managerial shareholdings are significantly different from those with low shareholdings (at p-value < 0.00). The average monitoring costs for those with high and low shareholdings are RM533, 436 and RM1,196,508 respectively. The t-test result for those companies with and without managerial shareholdings is also significant and shows the same pattern of result. The average monitoring costs of companies which have managerial shareholdings is RM656, 491, which is less than RM1,897,687, for those companies without such shareholdings.

5.0   Conclusions

Overall, the findings from this study indicate that, consistent with the earlier findings in western countries (Jensen & Meckling, 1976; O'Sullivan, 2000; Ang et al., 2000; Fleming et al., 2005; Nikkinen & Sahlstrom, 2004; Nimie, 2005), managerial ownership is a significant factor in influencing the companies' monitoring costs. The result also suggests that managerial ownership in Malaysian companies has a significant negative relationship with total monitoring costs as predicted by agency theory and convergence of interest hypothesis. Sensitivity analysis conducted on the direct managerial shareholdings only and indirect shareholdings only also reveal the same pattern of results.

However, the conclusions drawn from this study should be interpreted in a limited way, which would potentially represent opportunities for further investigation in future research. First, this study is a cross sectional study, where it uses one year data in 2006 only. Future research could extend the study to include more years of data, thus longitudinal studies can be conducted and further investigation on the impact of the organizational attributes on the demand for monitoring mechanisms in the short and long-terms can be analyzed. Secondly this study only examines one type of ownership structure which is the managerial ownership. Future research can also examine other forms of ownership structure which is unique to Malaysian companies, such as family ownership and government-link companies, in relation to their relationship with the demand for monitoring mechanisms.

ANTECEDENTS OF CEO SELECTION IN MALAYSIAN PUBLIC LISTED COMPANIES

ROKIAH ISHAK,
KU NOR IZAH KU ISMAIL,
SHAMSUL NAHAR ABDULLAH

Abstract

This study examines factors that influence Chief Executive Officer (CEO) selection whether from inside or outside of Malaysian Public Listed Companies. Among variables tested are firm performance, board attributes, ownership structure and incumbent power. Results indicate that firms that experienced high performance, had high proportion of outside board members and had high proportion of board members with multiple directorships are tend to select outsider as a successor. In contrast, firms that controlled by family and management and disposition their incumbent are more likely to select insider as a successor. These results were derived based on logit regression analysis on 142 succession events over a four- year period starting from 2002 to 2005.

INTRODUCTION

Top management succession events are of central concern in organizational theory. They are universal as when organizations survive long enough, they must somehow experience succession. The selection of the successor either from inside or outside the company will be determined by the board of directors. Once the board of directors has made the decision to hire a new top management, the next step is to find the right person. The board may decide to limit its search to inside candidates or it may decide to broaden its search by considering outside candidates.

A review of the literature on the succession subject suggests several viewpoints related to the selection decision such as adaptive view, inertial view, scapegoating view

and contingency view (Cannella & Lubatkin, 1993). The proponents of adaptive view argue that organization change or adapt in response to environmental challenges and that CEO selection decisions represent an important adaptation mechanism. According to the adaptive view, poor performance will increase the likelihood of top management turnover and when performance is poor, board of directors will favor outside candidates as they believe that outsiders are more capable of changing the mission, objectives and strategies of the organization than the insiders.

The second view of succession is inertial view and the proponents of this view believed that the selection process is relatively un-adaptive because of the large number of persons and vested interests involved (Shen & Cannella, 2002). Environments tend to change but the organizations, particularly large ones, resist changing, even when faced with poor performance. Thus, these organizations tend to select insider candidates which lower the link between organizational performance and outsider selection.

The third view of succession is scapegoating view. Boeker (1992) provides evidence that powerful CEOs, when confronted with poor performance, may try to deflect the blame onto weaker subordinates. These weaker subordinates are then dismissed while the CEO remains. The last view of the succession is a contingency view which is based on the sociopolitical approach to the CEO succession. Advocates of this view suggest that several sociopolitical influences moderate the relationship between performance and director decision making, causing the directors of different firms to react differently to similar performance information (Cannella & Lubatkin, 1993).

Based on CEO selection model suggested by Cannella and Lubatkin (1993), the motivation of this study is to adapt the same method with a few modifications to determine how these above mentioned factors influence the CEO selection in

363

Malaysian Public Listed Companies (PLCs). Malaysia is of interest not only because it is a developing country with an emerging capital market but also because of its unique corporate governance structure. The board of directors' structure follows the Anglo-American model while the ownership structure is more towards the Franco-Germany model, which concentrates more on family ownership and state or government ownership. Given an environment of Malaysian companies which are frequently held closely by founding family and relatively poor enforcement of shareholder's legal right, which is often thought to be associated with poor corporate governance, naturally leads to the question whether the CEO selection in Malaysian companies is a line with CEO selection in other companies around the world. Thus, this study tends to examine what are among factors that influence CEO selection in Malaysian public listed companies.

THEORETICAL DEVELOPMENT

Inside and Outside Succession

Different origins of the successor will contribute to different consequences. Pfeffer (1981) claims that the replacement of top management whether from internal or external sources can critically enhance or diminish the power of the organizational members and can also have important consequences for an organization's future strategies and structure. The definition of insider or outsider in this study follows the definition proposed by Dalton and Kesner (1985). They defined inside successor as a manager or employee promoted from within a firm and an outside successor as a newly appointed top management from outside the firm.

Corporate Performance and CEO Selection

Past performance may influence CEO's selection process. When choosing a new CEO, the board of directors will consider the abilities of each candidate that suit the competitive situation faced by the firm. Candidates with the abilities suited for a

continuation of the firm's current policies are more attractive when a firm is performing well than when it had performed poorly. Thus, the most suitable candidates for well performing firms are the insiders who will help to develop and implement these continuation policies. In addition, insiders often posses more of human specific capital as they have been working with the firm for a longer period. Furthermore, they may also have invested in firm's asset that they believed to be more valuable under their management than under others' management (Parrino, 1997).

On the other hand, candidates who are better able to change the direction of a firm are more attractive when things are not going well. Outside candidates who often have broader exposure and experience gained through their employment at other firms will introduce alternative ways to run a firm. Although outsiders generally possess less firm-specific human capital than insiders, the magnitude of this differences and the relative cost of inside and outside succession is likely to vary across industries. Boeker (1992) claims that the first and most frequently mentioned theory on succession focuses on the relation between company's past performance and the source of appointment. Lauterbach,Vu and Weisberg, (1999) prove that past performance affects successor choice. Their Pearson correlation supports their hypothesis that the poorer the firm's performance, the more likely are external successions. Their empirical evidence shows that firms in the lowest performance quintiles (poor performer) appoint mostly or about 60% from outside. In contrast, top performers tend to appoint from inside with the frequency of 82% of internal succession. Their findings support the argument that firm with poor performance needs to make some changes and the external succession becomes more likely. This is because the external succession is believed to conceive and implement fresh initiatives (Cannella & Lubatkin, 1993).

In contrast, Parrino (1997) and Dalton and Kesner (1985) argue that poor performance will lead to internal selection because it is not easy for the firms especially the larger ones to change their existing structure and policies due to many interest and power vested in these firms. In addition, Chung et al. (1987) also provide inverse evidence as they found high-performing firms are more likely to hire CEOs from outside the organization than are low-performing firm. From their sample of 65 low performing firms that had CEO changes, only nine solicited CEO from outside. In contrast, of 34 high-performing firms that had CEO changes, 10 (29%) hire outsiders.

Despite the inconclusive result from previous studies in terms of who is the best candidate, an insider or an outsider, according to the adaptive view it is reasonable to believe that the owner of poor performing firms will prefer an outsider as they perceive that an outsider will bring some changes to their companies, including the improvement of their companies' performance (Cannella & Lubatkin, 1993; Booker & Godstein,1993).

H1: Poorly performing firms are more likely to appoint their new top management

from external sources.

Based on conventional wisdom, it was held that high-performing firms should hire insiders to maintain superior performance, while low-performing firms should hire outsiders to turn around poor performance. However, empirical evidence is mixed. Due to the inconclusive result, studies by Boeker and Goodstein (1993) and Cannella and Lubatkin (1993) suggest that besides poor prior performance, other factors such as board attributes, ownership concentration and incumbent power do moderate the relationship between poor prior performance and outside succession.

Board of Directors' Attributes and CEO Selection

Board of directors is a collective entity and each of its members as individuals, has a fiduciary duty to the shareholders, and as a result is accountable to the shareholders. The main function of the board is to act as the representative of the shareholders and as the central body for decision making in a company. There are few board attributes that might influence the change of top management such as board size, board composition, board leadership and board members' multiple directorships.

Board Size and CEO Selection

Size refers to the number of directors who serves on the board (Zahra & Pearce, 1989). Scholars suggest that large board is more superior to the small ones because big groups have more capabilities and resources to solve group tasks. Larger firms are likely to benefit from having a larger board of directors because they have more external contracting relationship. Similarly, the governance of the firm would be more difficult when firm diverse its operation and required more insiders to provide specific information. In addition, this kind of firm might also require more outsiders in the board since broader skills would be required to adequately monitor the firm's multiple business line.

Further, Haleblian and Finkelstein (1993) explain that large groups can enhance problem-solving capabilities by increasing the amount of information that can be absorbed and recalled. Besides, larger board will increase the numbers of potential solution strategies and critical judgment to correct errors in inference and analysis. In addition, it will also increase the range of perspectives brought to bear on problems. Haniffa and Cooke (2005) argue that bigger boards may be constructive for some

367

companies as they provide diversity that would help companies to secure critical resources and reduce environmental uncertainties.

In contrast, Borokhovich, et al. (2006), claim that a small board is more effective than a larger one in making executive replacement decision. However, the authors add that due to small group members, the source of information, experience and contact with outside parties will be limited, which may cause the small groups to face difficulty in finding suitable candidates for the replacement especially from outsider. Therefore, larger network formed by a large board committee will enable them to find a suitable candidate to suit the vacant post. As board had more internal and external information about the firm, the board of directors in poor performing firms may have a higher tendency to select to an outsider as they believed that the outsider can improve the performance of the company via some changes made by outsider.

H2: Firms that have large board size will be more likely to appoint an outside successor.

Board Composition and CEO Selection

The composition of board has an impact to the internal control system of the firm and it is proved that a balanced board including both inside executives and outside executives will enhance the board's role as an internal control mechanism. With respect to the top management selection decision, agency theorists predict that inside directors tend to select the insider and oppose external candidates. The reason is because the internal candidates may add value to the firms since they are already involved in developing and implementing firm's current policies (Khurana, 1998). Due to their knowledge and involvement, the internal candidates are also the potential candidates for the top management positions.

368

A consistent statement was also proposed by Boeker and Goodstein (1993), who argued that managers in low performing firms will attempt to protect their interest and positions. Similar argument was also discussed by Mizruichi (1983) as he states that CEO succession process is inversely related to the proportion of insiders on board. When board is dominated by insiders, they will choose a CEO who poses a minimal threat of disruption and the most suitable person is typically someone within the firm whom they already know. As a result, firms with poor performance and controlled by more insiders in board composition tend to select insider for their job and interest security.

In contrast, agency theory also states that a board can potentially exercise control over managers and suggests that outsider dominated boards are acting more independently in making the CEO selection decision. Therefore, it is expected that the higher the proportion of the outside board members, the more likely it is that an outsider will be selected as the successor.

H3: Firms that have high proportions of outside board members will be more likely to appoint an outside successor.

Board Leadership and CEO Selection

Advocates of stewardship theory suggest that the joint structure provides unified firm leadership, and removes any internal or external ambiguity regarding who is responsible for firms, process and outcomes. Haniffa and Cooke (2002) claim that efficiency in monitoring management can be enhanced through chairman-CEO duality as less contracting is needed and information asymmetries is reduced. However, Pi and Timme (1993) claimed that cost-efficiency and return on assets are lower when the

CEO is also the Chairman. The argument is because the CEO/Chairman will have concentrated power base which will allow the CEO to make decisions for his/her own-self interest at the expense of shareholders.

Morck et al. (1988) suggest that the number of titles held by a single individual may indicate a power vested by that individual. Regarding the selection of the successor, Cannella & Lubatkin (1993) claim that a CEO who holds both Chairman and CEO position, will increase the power of the incumbent CEO. Due to the power that they have, they will intervene during the selection of the new successor. They tend to nominate a potential candidate and as to maintain their status quo, they may select an insider as the successor. Thus;

H4: Firms that separate both CEO and chairman titles will be more likely to appoint an outside successor.

Board Multiple Directorships and CEO Selection

Social network theory suggests that managers with multiple directorships are perceived to be more prestigious in their social environment and have more power relative to the board of directors since this power is derived from the recognition given by outsiders (Phan & Hoon, 1995). Meanwhile, Pfeffer and Salancik (1978) view board with multiple directorships as an instrument for reinforcing intercorporate exchanges. Fairchild and Li (2005) discuss that a board which consists of directors who hold more than one directorship will be considered as a high quality board due to the skills and power obtained. These skills and power are believed to contribute in guiding and evaluating the managerial behavior of the corporation.

In the case of selection process, if the board decides to hire an outside candidate, the main question that arises is how to find the suitable candidate. One possible answer to that question is a multiple directorships. As explained by Haniffa & Cooke (2005), a director with multiple directorships is viewed as an information provider, whether inside or outside the organization. The multiple directorships will provide useful information about the external candidates that have a potential to fill the vacant place. This statement is supported by Khurana (1998) as he claims that directors who sit in more than one board are viewed as a communication network which can facilitate the exchange of information. Due to convincing suggestion by board regarding who is the best candidate, low performing firms which has board member with multiple directorships is expected to favor an outside successor than an inside one.

H5: Firms that have board members with multiple directorships will be more
likely
to appoint an outside successor.

Ownership Structure

Ownership structure significantly affects the likelihood of a change in top executive as it has an impact on both internal monitoring efforts and the effectiveness of control monitoring efforts. This study will on focus on how family ownership and managerial ownership influence the CEO selection in Malaysian PLCs.

Family-controlled Firms and CEO Selection

Family-controlled firms normally planned the succession of their top management by electing the heir apparent to be groomed up. This action is taken in order to make sure that their business empires will continue under the same family management. In the case of family controlled corporations, profitability is not the only goal (Allan & Panian

1982). Direct control by a family member, with all the power and privileges that this control confers on the other members of the family, may became a goal in itself. Indeed, controlling families may be willing to sacrifice some degree of corporate profitability in order to retain some degree of direct family control over the corporation. The similar argument was raised up by Chami (1997) who argued that family values like trust, altruism and paternalism can create an atmosphere of love for business and a sense of commitment. Therefore, due to commitment and loyalty, even in the case of poor performance, the family-controlled firms will select one of their family members as the successor.

H6: Firms that are controlled by families will be more likely to appoint an inside successor.

Managerial Ownership and CEO Selection

Agency theory discusses that there will be a convergence of interest between agent and principal. One way to solve this problem and to make the top management's interest align with shareholders' interest is by allowing the top management to have some shares in the company. As the management owns some portion of company's share, they are now becoming the owners of the firms. As a result, they will put in their best efforts to enhance the firm's performance in order to maximize their own wealth.

Managers who own a significant amount of ownership in firms may influence the selection of the successor and they will have a higher tendency to naming an insider as a successor (Boeker 1992; Boeker & Goodstein, 1993). They also suggest an insider who will be less likely to initiate such large-scale changes as the dismissal of managers. Based on this argument, Boeker and Goodstein (1993) predict that poorly performing firms with high proportions of ownership by management will be less likely

to choose an outside successor. Consistent with their prediction, their results revealed that there is a negative relationship between outside successor and managerial ownership.

A study by Shen and Cannella (2002) also provides a similar result as the researchers found that managerial ownership plays an important role in heightening the likelihood of CEO dismissal followed by inside selection. This view implies that, because of the fear of losing their jobs and their power, the managers tend to select an insider to become the successor, who turns out to be among their click member. Therefore, in the case of low performing firms, the board believed that they need to switch to the outsider, but the desire for certainty and job security will prohibit them from selecting the outsider (Boeker, 1992). Thus, the insider will be their choice for the successor.

H7: Firms that are controlled by management will be more likely to appoint inside

successor.

Turnover Type and CEO Selection

In the selection process, turnover type might also influence the origin of the successor. Based on conventional wisdom, it was held that low-performing firms which are involved in forced turnover should hire outsiders to turn around the poor performance. However, empirical evidence is in contrast with the adaptive view of succession which predicts that forced turnover will lead to outside succession. For example, a study by Parrino (1997) who divided turnover into forced and voluntary, found that forced turnover due to poor performance lead to more internal succession than external succession. Based on 127 sample of forced turnover related with low corporate

performance, 64 or 50.4% were replaced by insiders. Meanwhile, of the 850 CEOs who depart voluntarily, 766 or 90.1% were succeeded by the insiders. A similar finding was reported by Shen and Cannella (2002) as they found that 38 out of 65 dismissed CEOs (58%) in their study were succeeded by insiders. The authors claimed that their result is not in line with the adaptive theory due to power dynamics within top management themselves. This power had influence the selection process of the successor which leads to inside succession rather than outside succession.

H8: Firms that experience forced turnover will be more likely to appoint an insider

than an outsider as a successor.

Predecessor Disposition and CEO Selection

Cannella and Lubatkin (1993) claim that disposition or the change in position from one position to another within the firm signals that the incumbent knowledge and expertise are still needed by the firm. Friedman and Singh (1989) state that firms with a healthy financial performance tend to retain their incumbent top management whereas the poor performing firms tend to dismiss their top management. As the incumbent top management is   still holding a post in the firms, they might also influence the selection of the successor. Firms that retain the former manager signal their preferences for some continuity. Therefore, in the case of the successor selection, an insider is more preferable than an outsider (Lauterbach, Vu & Weisberg, 1999). The reason is the insider will continue the existing policies and strategies established by the firm. Despite facing a performance problem, firms that disposition their incumbent top management are expected to select an insider due to their security and other board members security (Boeker, 1992).

H9: Firms that disposition their incumbent top management will be more likely

to

appoint an inside successor.

METHODS

This study will focus on CEO succession during four years interval starting from 2002 to 2005, which is after the financial crisis and surrounding the publication of Malaysian Code of Corporate Governance (MCCG) in March 2000. Year 2002 is selected as a starting year following to the year of financial crisis in 1997-1998 and the implementation of MCCG. A large number of companies suffered a financial distress during the 1997-1998 periods and are expected to reorganize its financial and operation policy in order to expand their businesses.

Measures

Unit analysis of this study is CEO succession in Malaysian PLCs. The population of this research comprise of companies that are traded and listed on the Main Board and Second Board of Bursa Malaysia including both good and low performing firms. There were 142 succession events occurred during four-year period for both Main and Second Board of Bursa Malaysia.

Dependent Variable: Inside or outside succession

The dependent variable of interest in this study is whether a CEO successor came from inside or outside the firm. This data is available from the announcement made by the company in the Bursa Malaysia website regarding the change of firm's management team. The information will disclose the profile of the successor including his or her previous position before being elected as the new CEO. Successor origin, measured for each firm each time a succession occurred is coded as 1 if the successor is from

outside the firm and 0 if otherwise. The definition of insider or outsider in this study follows the definition proposed by Dalton and Kesner (1985). They defined inside successor as a manager or employee promoted from within a firm and an outside successor as a newly appointed top management from outside the firm.

Corporate Performance

This study employed two categories of performance measurements which are accounting based (ROA) and market based performance (Tobin's Q). The ROA is calculated as the ratio of accounting earnings before interest and taxes to the book value of assets. The Tobin Q is measured as ratio of the market value of common shares plus total debt divided by the book value of total assets of the company. This study used two-year average performance for both measurements because an organization may not ordinarily react to poor performance by replacing its CEO in the same year the poor performance occurs (Boeker & Goodstein, 1993).

Board Attributes

Information on the board of directors for each firm in the study is compiled by the firm and disclosed in the corporate information and directors profile section in the firm's annual report.

Size

Board size is measured as the number of board members (Zahra & Pearce, 1989).

Composition

Board composition is measured as the proportion of non-executive directors (NEDs) to total number of directors on the board of the company. (Boeker & Goodstein,1993; Borokhovich et al. 2006).

Leadership

Dual title is coded as a dummy variable. Coding is 0 if the outgoing CEO also holds the title "chairperson" and as 1 if another person is a "chairperson" (Cannella & Lubatkin, 1993).

Multiple Directorships

Multiple directorships are determined based on the number of directorships held by board members. It is measured as the proportion of directors on board of the company having at least one additional directorship in another company to total numbers of directors on board (Haniffa & Hudaib, 2006).

Ownership Structures

Various attributes of equity ownership structure may influence the incidence of top management change due to different levels of corporate governance.

Family-controlled firms

A family firm is defined as a proportion of ordinary shares owned by family directors of the company as a group to total shares outstanding. (Haniffa & Cooke, 2002).

Managerial Ownership

Managerial ownership is operationalized as the function of ordinary shares owned by executive directors of the company as a group to total shares outstanding (Pergola, 2005).

Turnover Type

By examining the announcement made by the company regarding top management turnover, the turnover type will be classified as voluntary or forced turnover Succession theory suggests that there are at least four voluntary scenarios, namely the relay succession, normal retirement, early retirement and death or poor health (Friedman &

Singh, 1989; Cannella & Lubatkin, 1993). Regarding forced turnover, Dahya et al. (2002) and Huson, Malatesta and Parrino (2004) identify forced turnover by examining the report released by the press including the Financial Times and Wall Street Journal. They labeled turnover as a forced turnover when the news articles state that the executive was "fired" or "resigned" and in both cases the CEO must be less than 60 years old. In addition, if the announcement did not report any reason for the departure as death, poor health, or the acceptance of other position elsewhere or within the firm stated, then the departure is also classified as forced turnover. Further, removal is also considered as forced turnover since top management are removed before the expiration of their three years term (Kang, 2002). For the purpose of this study, classification between forced turnover and voluntary turnover will be based on the reason stated in the change of management announcement made by a company in the KLSE website as suggested by Huson et al. (2004) and Dahya et al. (2002). A dummy variable is used to determine turnover type. "1" is for forced turnover and "0" is for voluntary turnover.

Predecessor Disposition

Incumbent disposition is a binary variable. Coding is 1 if the CEO stays in the company with a new position other than CEO, and 0 if the CEO leaves the firm (Friedman & Singh, 1989).

RESULTS

Table 1 show means, standard deviations and correlations among variables This study employed logistic regression to explain the relationship between performance (both ROA and Tobin's Q), board composition, firm ownership, turnover type and predecessor disposition. Two logistic regressions were used to cater for two different performance measurements employed in this study. However, the result based on ROA performance measurement is not discussed in this study as the coefficient of ROA variable is not significant.

TABLE 1
Descriptive Statistics and Correlations*

Variables	Means	Std Dev	1	2	3	4	5	6	7	8	9
1. Outsider	0.54	0.50									
2.Performance	1.19	0.84	0.31								
3. Board size	7.85	1.98	0.05	0.02

* N= 142. Correlations greater than 0.19 are significant at $p < 0.05$

Hypothesis 1 predicts that performance will have a negative effect on the choice of an outside successor. However, the finding of this study does not support the hypothesis as the result in Table 2 shows that there is a positive relationship between performance and outside successor. This result implies that the better the performance of a company the more likelihood the outsider will be selected as a successor. Result shown in table to also support hypothesis 3 and hypothesis 4 for board attributes. The coefficients for outside board member proportion and board members' multiple directorships are both positive and significant. These results indicate that the higher proportion of outside directors on the board of company and the more board members with multiple directors the more likelihood the outsider will be chosen as a successor. However, hypothesis 2 and hypothesis 5 are not supported in this study. This finding indicates that the board size and the separation between CEO and chairman titles do not influence the selection of the outsider as a successor.

For ownership structures, both hypothesis 6 and hypothesis 7 show an inverse relationship between family ownership, managerial ownership and outside selection. These finding revealed that outsider are not preferable in both family-owned and managerial-owned company. The inside successor is most welcome in this two type of firms in order to maintain their status quo, control and job security. There is a negative relationship between type of turnover and the choice of outside successor which indicate that forced turnover does not lead to outside succession. However the coefficient is not significant and hypothesis 8 is not supported. Hypothesis 9 stated that if the incumbent CEO is given another post in the same company, he/she will intervenes in new CEO selection. He/she will have a higher tendency to naming an insider to be a successor for his security and other board member security. This hypothesis is supported as the coefficient of predecessor disposition showed a

negative significant sign towards outside selection which implies that insider is preferable when the incumbent CEO is still holding a post in a company.

Overall, the finding of this study support that firm performance, board attributes, firm ownership, turnover type and predecessor disposition influence the successor choice. The model has a chi-square of 142.667 (p=0.000) with 9 degree of freedom indicating that the model was able to distinguish between outside selection and inside selection. The model as a whole explained between 63.4 percent (Cox and Snell R-squared) and 84.7 percent (Nagelkerke R-squared) of the variance in outside selection. The McFadden Psuedo R-squared is 72.7 percent which indicates a higher relationship between dependent variable and independent variables. The overall percentage of correct classification is 88.7 percent shows an improvement from 53.5 percent before the inclusion of independent variable. The model was able to correctly classified 88.5 percents of companies which select outsider as a successor and 89.1% percent companies which select insider as a successor.

DISSCUSSION AND CONCLUSIONS

The major purpose of this study is to identify factors that influence the selection of CEO successor whether insider or outsider by Malaysian PLCs. This study examined the interdependent effects of five sets of antecedents: corporate performance, board attributes, ownership, turnover type and predecessor disposition. This study began with examining the relationship between company performance and outside selection. Both performance accounting based (ROA) and market based (Tobin's Q) showed a positive sign of relationship, however only the Tobin's Q performance showed a positive significant coefficient. This result is contradicted with most previous studies as those studies found a negative relationship between performance and outside selection. However, the finding of this study is a line with Parrino (1997) and Dalton and Kesner (1985) who found that poor performance firms are more likely to choose an insider as a successor because they do not want to change their existing structure and policies due to many power vested in these firms. In addition, they added that, it is difficult for

the low performing firms to find a suitable outside candidate who capable to turnaround its performance. Furthermore, study by Chung et al. (1987) also found that high performing firms are more likely to hire CEOs from outside the organization than are low performing firms. They argue that outside selection is viewed as an adaptive behaviour which is appreciated by investors.

Due to inconclusive result regarding relationship between performance and outside selection, Cannella and Lubatkin (1993) suggest that there might be other factors that influence CEO selection choice such as board of directors, firm ownership and predecessor power. This study also examine the above mention factors and find that the higher proportion of outside members in the board of company has a positive significant influent to the CEO selection. This finding support studies by Boeker and Goodstein (1993) and Borokhovich et al. (2006) which found that firms with high proportion of insiders on their boards of directors will be less likely to choose the outside as a successor. This study also revealed that firms which board members hold more than one directorship will tend to select outside as a successor. This finding support social network theory which argues that board members who sit in more than one board are viewed as an information provider. They are able to provide useful information about the external candidates that has a potential to fill the incumbent CEO post. Other board attributes like board size and CEO duality are not significant elements in determining the outside selection as both variables are not significant.

Both hypotheses on ownership structures (i.e family and managerial) are supported as this study found a negative relationship between family-owned and managerial-owned firms with outside selection. This finding implied that both family and managerial owned firms prefer insider than outsider in order to maintain their control and job security. Previous studies discussed that forced turnover which normally due to

poor performance will lead to outside selection. However, this study does not found a significant result regarding turnover type and outside selection.

Former CEOs are often retained on the board as Chairman of the Executive Committee, especially when firms are enjoying healthy performance. The aim is to utilize the CEOs valuable knowledge on the company and business. This study also found an inverse relationship between outside selection and predecessor disposition. This result showed that the existence of a predecessor in the board might also influence the selection of the successor because it is reasonable to assume that firms that retain the former manager in their organizations signal their preferences for some continuity (Lauterbach, et al. 1999). Thus, an inside succession is preferable than outside succession when incumbent top management is still holding an official position in the company.

The major implication of this study is that poor performance does not lead to outside successor which is different from previous studies. A possible explanation for this finding is may be because high-performing firm also want to change their structure and policies and one possible way is by replacing their incumbent CEO with an outsider. The selection of outsider as a successor is viewed as an adaptive view which attracts investors' attention that may increase firm's future performance. This study also has important implications for corporate governance and ownership structure of organizations. Firms whose boards are dominated by outsider and board members hold more than one directorships in other companies are tend to select the outsider as a successor. This finding support the social network theory which claim that boards have higher proportion of outsider and board members that have multiple directors will have more information and communicate with outsider. As a result, they are able to find a suitable outside candidate to fill the vacant post. In contrast, firms that control by

family and management are more likely to choose insider as a successor for continuity of policies, structure, control and security. They believed that the insider will provide a smooth transition and stability since they are well acquainted and have participated in developing the existing corporate strategies.

Other implication of this study is the power of incumbent CEO also influences the choice of the successor. Firms that retain the former manager tend to select the insider as a successor due to their security and other board members security.

As a conclusion past performance, board attributes, firm ownership, predecessor power and turnover type composition do influence the CEO selection choice in Malaysian PLCs. Firms tend to select an outsider as a successor when firms perform well, have a higher proportion of outsider as a board members and have more board members that hold more than one directorship. In contrast, firms that owned by family, management and retain the incumbent CEO are more likely to choose insider as a successor.

Abstract

This paper examines the relationship between internal governance mechanisms, namely the role of boards and earnings quality focusing on two important characteristics of board effectiveness: (1) board composition (i.e. board independence); and (2) board expertise (i.e. financial, governance and firm-specific expertise). Using data from 831 non-financial companies, listed on Bursa Malaysia's Main Board over the period 2003-2005, this study finds a positive and significant association between board governance and firm-specific expertise and earnings quality measured by the accrual quality model. Additional directorships held by board members and longer average tenure held by independent directors are found to be two important determinants of an effective board. No evidence of association was found between board financial expertise and earnings quality. Concerning board independence, this study finds a significant but contrary sign on the relationship between board independence and earnings quality and casts doubt on whether independent directors in Malaysia are truly independent when inside directors dominate the board.

1. INTRODUCTION

Concerns about corporate governance in East Asian countries emerged as a result of the East Asian financial crisis in 1997/1998. The crisis exposed the consequences of weak governance and poor governance standards were blamed indirectly in part for the crisis (Nam and Nam, 2004). This weakened foreign investors' confidence in the East Asian capital market, including Malaysia (Leng, 2004; Abdul Rahman and Haniffa, 2005). Further, the tragic collapses and losses of giant companies such as Enron Corporation, WorldCom and Tyco International in the United States (US), which is known to have the best regulated and most efficient capital market in the world, highlights the critical need to improve the corporate governance system in both developed and developing countries. These together with other scandals such as Parmalat in Italy, Vivendi in France and Royal Ahold in Netherlands, followed by revelations of misrepresentation of financial statements, have drawn attention to

corporate governance reform around the world. There is urgent need to improve the quality of reported earnings as the capital market needs precise and unbiased financial reporting to value securities and encourage investors' confidence (Pergola, 2005).

Consequently, many countries[48] have been proactive in improving and strengthening corporate governance systems. The main focus is to enhance the quality of the board of directors so that shareholders' interest can be better protected. Malaysia introduced the Malaysian Code on Corporate Governance 2000 (MCCG 2000) outlining the principles and best practices for corporate governance. In the MCCG 2000, the role, composition and structure of the board of directors are viewed as the most crucial elements for effective corporate governance mechanisms. The Code recommends that firms have a well balanced and effective board to take the lead role in establishing best practice in corporate governance. A well-balanced board is defined as having a balance of executive directors and non-executive directors, including independent non-executive directors, to ensure effective decision making by the board with no domination from individual or small groups of individuals (MCCG, 2000). The Code also requires that non-executive directors have the necessary skills and experience and be persons of calibre and credibility in order to bring independent judgment to the board.

This paper contributes to the literature on the association between board characteristics and financial reporting quality in several ways. First, this study provides further insight into the relation between the roles of board to earnings quality using a broad measure of board characteristics based on the work of Bedard *et al.* (2004). While most prior studies on board of director's characteristics focus mainly on the role of board independence, this study also examines their expertise to effectively monitor the financial reporting process. Second, this study applies the accrual quality model developed by Dechow and Dichev (2002) that captures one aspect of the quality of accruals and earnings. The use of the accrual quality model, as an improved measure of earnings quality, is to overcome the weaknesses of measurement errors in the earnings management model (i.e. absolute discretionary accrual) in measuring earnings quality[49]. Among seven earnings attributes to define earnings quality (i.e. accrual quality, persistence, predictability, smoothness, value relevance, timeliness and

[49] See McNichols (2000) on the research design issues in earnings management studies for detailed discussions and evidences on aggregate accruals models possible misspecification to characterize discretionary behaviour.

conservatism) evaluated by Francis *et al.* (2004) to investigate the relationship between cost of equity and attributes of earnings, the accrual quality model outperforms the other attributes that were characterized as accounting-based and market-based attributes. Third, this study focuses on a specific country study, i.e. Malaysia to provide a better understanding of the link between governance and financial reporting in emerging countries. Concentration on a country or region helps to control for different factors that affect studies across countries, thus providing a deeper understanding of the issues being examined, especially in jurisdictions outside of the US and the UK (Jaggi *et al.*, 2007).

Despite the general belief that greater independence of the board is associated with greater financial reporting quality, this study finds a contrary but significant relationship between board independence and earnings quality. Contradictory to the agency theory prediction, a higher proportion of independent directors is associated with a lower quality of reported earnings. Fuzzy findings from this study may be due to the fact that the ownership structure in Malaysia is highly concentrated in the hands of inside directors, who are normally family members. This creates a real danger that self-interested behaviour of managers goes unchallenged by independent directors and may lead to expropriation of the minority shareholders' wealth. In order to focus beyond the independent directors' monitoring role, this study also includes board expertise variables as complementary characteristics that might reasonably enhance the effectiveness of boards. Interestingly, this study finds a positive and significant association between governance and firm-specific expertise and earnings quality. Additional directorship held by board members to gain governance expertise and the longer average tenure of independent directors to acquire firm-specific expertise are found to be significantly associated with greater earnings quality. However no association is found with regards to the relationship between board financial expertise and earnings quality.

The remainder of this paper is organized as follows. Section 2 discusses the background for the study and contains a review of the relevant literature. Section 3 outlines and explains the sample selection, research method and variable measurement. Section 4 analyses and discusses the research results. Finally, the conclusions, limitations and suggestions for future research are considered in Section 5.

2. BACKGROUND OF THE STUDY AND LITERATURE REVIEW

2.1 Malaysian Code on Corporate Governance

Historically, Malaysia was a former British colony. Hence, the development of company law in Malaysia closely follows the pattern of the UK's company legislation. The Malaysian accounting and auditing standards replicate those found in the UK as well as other commonwealth countries such as Australia and New Zealand (Gul, 2006). Although there are broad similarities with regards to accounting and regulatory environments with the US and the UK, the Malaysian corporate sector operates in a different institutional environment. Like other East Asian countries, many Malaysian firms are closely owned or privately held with the principal shareholders typically playing an active role in management (Abdullah, 2006).

Davis-Friday *et al.* (2006) show that the value relevance of earnings and book value in four Asian countries, Indonesia, South Korea, Malaysia and Thailand were significantly reduced during the Asian financial crisis and is related to the countries' weak corporate governance mechanisms. In the post-Asian financial crisis and post-Enron era, corporate governance reforms have become the most important agenda issue globally. In Malaysia, the financial crisis provided an impetus for corporate governance reforms with the publication of the Report on Corporate Governance in February 1999. The aim was to improve disclosure and good corporate governance practices in Malaysia and re-establish the investor's confidence in the Malaysian capital market (Report on Corporate Governance, 1999). Due to the recognition of corporate governance in Malaysia, the Finance Committee then issued the Malaysian Code on Corporate Governance (MCCG) in March 2000. Given the historical connection between Malaysia and the UK, the Malaysian Code was basically modelled after the UK Combined Code on Corporate Governance (Ow-Yong and Guan, 2000).

Corporate governance as defined by the Finance Committee on Corporate Governance in Malaysia is *'…the process and structure used to direct and manage the business and affairs of the company towards enhancing business prosperity and corporate accountability with the ultimate objective of realizing long term shareholder value, whilst taking account the interests of other stakeholders'* (Report on Corporate Governance

1999, p.52). The definition emphasizes the contribution of corporate governance to both business prosperity and accountability to enhance shareholder value so that they will receive an appropriate return on their investment. Corporate governance will serve as a set of rules to persons who have the power to direct and manage the firm, to enable them to make accountable decision-making.

The Malaysian Code was fully implemented in January 2001 with a revamp of the listing requirements of Bursa Malaysia [50]. The Revamped Listing Requirements represent a major milestone in corporate governance, creating an environment that demands higher standards of conducts and a higher quality of disclosure from corporate governance participants in Malaysia. In order to enhance the transparency of public listed companies in Malaysia, listed firms with a financial year ending after 30 June 2001 onwards are required to include in their annual report – the statement of corporate governance, a statement of internal control, composition of the board of directors, composition of audit committee, quorum of audit committee and any additional statements by the board of directors.

The report focuses on the monitoring functions of boards to enhance the quality of internal controls and financial reporting. Among the crucial recommendations in the Code are the inclusion of one third of the board to comprise of independent non-executive directors, the separation of powers between the chairman and chief executive officer, effective board structure and procedures and a formal selection process of directors with the establishment of a nomination and remuneration committee comprised solely of non-executive directors. Additionally the revised MCCG 2007 [51] enriches the role of the nomination committee by requesting that when candidates are recommended for directorships they should have the necessary skills, knowledge, expertise, experience, professionalism, and integrity to strengthen and ensure the board discharges its roles and responsibilities effectively. The following discussion focuses on two main issues of an effective board i.e. board composition and board expertise.

2.2 Board Composition

---

[50] Prior to April 2004, Bursa Malaysia was known as Kuala Lumpur Stock Exchange.
[51] The aim of the Revised MCCG 2007 is to further strengthen corporate governance practices in line with developments in the domestic and international capital markets.

The board of directors' role as a monitoring tool is viewed as the most crucial element for effective corporate governance mechanisms to enhance the quality and integrity of accounting information (see e.g. Cadbury Report, 1992; Malaysian Code on Corporate Governance, 2000; Singapore Code on Corporate Governance, 2001; Higgs Report, 2003). Fama and Jensen (1983) theorize that the board of directors is the most important internal control mechanism that is responsible to monitor the actions of top management. They represent the interests of the firm's shareholders by setting strategies, policies and goals that maximize shareholders' wealth (Fama and Jensen, 1983).

From an agency theory perspective, the board of directors is used for monitoring executive opportunistic behaviour. The theory emphasises the need for greater proportion independent directors to monitor any self-interested actions by managers (Nicholson and Kiel, 2007). Independent directors have more incentive to effectively monitor management because of a strong need to develop their reputations as expert decision makers (Fama and Jensen, 1983). With their independence and objectivity, independent directors have the ability to resist pressure from the firm to manipulate earnings and are better able to monitor the earnings process (Machuga and Teitel, 2009).

Nevertheless, empirical evidence on the association between independent directors and financial reporting quality is mixed. Some studies, especially from countries with a diffused ownership structure such as US and UK, have found that having greater proportion of independent directors on the board improves financial reporting quality (Beasley, 1996; Peasnell *et al.*, 2000; 2005; Klein, 2002; Davidson *et al.*, 2005). Other studies from countries where the ownership structure is highly concentrated, either do not have found a link between independent directors and improved firms' financial reporting quality (Abdullah and Mohd Nasir, 2004; Park and Shin, 2004; Abdul Rahman and Mohamed Ali, 2006; Hashim and Susela, 2008a; Siregar and Utama, 2008; Machuga and Teitel, 2009) or document contrary findings with agency theory predictions (Norman *et al.*, 2005; Klein *et al.*, 2005; Hashim and Susela, 2008b). This raises doubt as to whether the requirement for a majority of independent directors is appropriate in countries with a concentrated ownership structure, which have lack of qualified independent directors and are controlled by a single majority owner (Barton *et al.*, 2004).

The MCCG 2000 views that good governance rests firmly with the board of directors. The Code requires one third of the board to comprise of independent non-executive directors. The Listing Requirements stipulate that at least two directors or one third of the board, whichever is higher, must be independent. Despite the conflicting results from prior studies, it is hypothesized that:

H_1: Firms with an independent board of directors are likely to have greater earnings quality.

2.3 Board Expertise

Daily *et al.* (2003) suggest that over emphasis on directors' oversight role to the exclusion of alternative roles such as resource, service and strategy roles is one potential explanation for limited evidence from board oversight functions. To perform specified duties and responsibilities, the board members must consist of a diverse collection of skills and competencies (Reilly, 2003). Having board members who lack knowledge and experience actually threatens the firm's overall performance due to the inability to deal with issues affecting the firm's business (CFA Institute, 2005). Three aspects of board expertise, i.e. financial, governance and firm-specific expertise as discussed by Bedard *et al.* (2004) are examined in this study.

2.3.1 Financial Expertise

Peasnell *et al.* (2000) believe that the ability of non-executive directors to perform a monitoring role, in reducing earnings management activity, is only pertinent when they are capable of identifying cases of earnings management that falls within the scope of the board of directors' expertise. George (2003) argues that poor financial reporting quality may result from a board member who has no technical expertise. To be effective in addressing issues relating to the financial information of the company, the directors should have a sound financial background and must at least be able to read and understand the balance sheet (Renton, 2003).

The study by Xie *et al.* (2003) finds that boards of directors composed of corporate or investment-banking backgrounds are negatively related to the level of earnings management and suggests that independent directors with corporate and financial backgrounds are an important determinant of board monitoring effectiveness as they have a better understanding of how earnings are being

managed. Bedard *et al.*, (2004) observe that the presence of a financial expert on the audit committee is negatively related with the likelihood of aggressive earnings management. Although Park and Shin (2004) fail to find significant evidence between board independence and accrual management, they do find evidence that the presence of officers from financial intermediaries on the board are helpful in limiting abnormal accruals when the unmanaged earnings are below the target. They suggest that experienced outside board members actually helps them understand the firms and its people better and thus enhances their governance competencies.

The Blue Ribbon Panel addresses the issue of the financial sophistication of audit committee members in preventing earnings management behaviour. In Malaysia, the revised MCCG Code 2007 requires all members of audit committees to be financially literate. This is so they are able to understand and interpret financial statements to effectively fulfil their role in monitoring the company's system of internal control and financial reporting. Additionally, the Code also requires at least one audit committee member to be a member of an accounting association or body. It is hypothesized that:

H_2: Firms with financial expert board committee members are likely to have greater earnings quality.

2.3.2 Governance Expertise

'Economic theory suggests that one of the main factors motivating directors to act in shareholders' interests is their desire to establish a reputation in the labour market for directorships, thereby increasing the value of their human capital' (Peasnell *et al.* 1999, p.106). Additional directorships signal the competence of directors in the managerial labour market and provide a platform for directors to gain governance expertise (Bedard *et al.*, 2004). Governance expertise refers to the ability of the director to appreciate the differences between management and direction and to have a good understanding of the board's operations, including the legal framework within which they operate (Renton, 2003).

Additional directorships help the directors to be more transparent as well as more sensitive to protect their reputations, thus, creating an incentive for them to perform

well (Haniffa and Cooke, 2005; Vafeas, 2005). However, this is dependent upon the time and effort they spend, as a large number of outside directors may limit the time they can devote to a particular firm, which in turn may decrease their governing effectiveness (Bedard *et al.*, 2004). In US study, Bedard *et al.*, (2004) find that the average number of cross-directorships of independent audit committee members is significantly related to both income-increasing and income-decreasing earnings management. They find that the greater the additional number of other directorships held by board members, the lower the likelihood of earnings management activity of the firm. Similarly, a study by Norman *et al.* (2005) for Malaysian study reports a significant and negative association between multiple directorships and earnings management in firms with negative unmanaged earnings. They suggest that multiple directorships serve as important governance mechanisms in mitigating earnings management activity and any attempt of earnings management would jeopardize directors' future in the managerial labour market.

For Malaysian cases, the Bursa Malaysia adopts restriction in the number of directorship per director in its listing requirement in 2002. The maximum number of directorship is ten in public companies and fifteen in private listed companies to ensure the directors to perform their duties effectively with less commitment, resources and time available (Zulkafli *et al.*, 2005). It is hypothesized that:

H$_3$: Firms with governance expert board committee members are likely to have greater earnings quality.

2.3.3 Firm-specific Expertise

Other important characteristics to determine the expertise of the board come from studying the impact of board tenure on financial reporting quality. Firm specific expertise is acquired through experience as a member of the board by developing more knowledge of a company's operations and its executive directors (Bedard *et al.*, 2004). Beasley (1996) finds negative and significant association between the number of years of board service for outside directors and the likelihood of financial statement fraud. He believes that the ability of boards to monitor management effectively is consistent with the increased number of years they serve.

Nevertheless, Vafeas (2005) identifies conflicting theoretical views on the impact of independent director tenure length and board effectiveness. While longer average tenure is associated with greater experience and knowledge about the firm's operation, she argues that too long a board service in the same company will compromise their independence as they are more likely to befriend management and be less critical about the quality of financial reporting. A survey by Peasnell *et al.* (1999) finds that on average the length of tenure for non-executive directors in the UK is five years with twenty five percent of the sample having served the company more than six and a half years. Their findings cast doubts about the independence of the board who serve on boards too long. Xie *et al.* (2003) find that the longer the tenure of directors, the less effective they became as they may co-opt with management. They find a positive instead of negative relationship between board tenure and the level of discretionary accruals. Despite the conflicting results from prior studies, it is hypothesized that:

H_4: Firms with firm-specific expert board committee members are likely to have greater earnings quality.

3. METHODOLOGY

3.1 Sample Selection

The initial sample of the study consists of all companies that were listed on the Main Board of Bursa Malaysia for the period 1998 to 2006. At the end of the year 2006, there were 649 financial and non-financial companies listed on the Main Board. Due to different statutory requirements, all banks, insurance and unit trusts companies as well as utility companies were excluded from the population of interest, reducing the sample size to 592 non-financial companies.

For a sample of three years period, nine years complete accounting data, *t = 1998-2006* is required to estimate accrual quality. For that reason, the number of data observations is further reduced to 424 non-financial companies with complete data for current assets, current liabilities, cash, change in debt in current liabilities, cash flow from operations, revenues and property, plant and equipment. A firm is included in the year *t* sample if data is available for year's *t-4* to *t*. Any firms that were de-listed within

years 1998 to 2005 were also excluded from the population of interest due to incomplete data. As consistent with prior research (Davidson *et al.*, 2005; Abdul Rahman and Mohamed Ali, 2006) industries with less than 8 firms were also eliminated from the analysis. Further, 139 companies were excluded as the required financial and corporate governance data was not available, resulting in a final sample of 277 companies from 2003 to 2005, giving a total of 831 firm-year observations with complete data for earnings quality and board of directors' characteristics.

3.2 Regression Model

This study uses a linear multiple regression analysis to test the association between the dependent variable of earnings quality and the independent variable of board independence, board financial expertise, board governance expertise and board firm-specific expertise.

$$EQ = \beta_0 + \beta_1\,BIND + \beta_2\,BDFINEXP + \beta_3\,BDCROSS + \beta_4\,BDTENURE + \beta_5\,BDSIZE + \beta_6\,LNSALES + \beta_7\,LEV + \beta_8 ROA + \beta_9 BIG4 + \beta_{10} DUM\_YR04 + \beta_{11} DUM\_YR05 + \varepsilon\ldots \ (1)$$

Where:
EQ	= measured by accrual quality based on Dechow and Dichev (2002) model
BIND	= proportion of independent non-executive directors to the total number of directors on the board of the company
BDFINEXP	= proportion of directors on the board with financial expertise to the total number of directors
BDCROSS	= proportion of directors on the board, with directorships in other companies, to the total number of directors.
BDTENURE	= average number of years of board service of independent non-executive Directors
BDSIZE	= total number of directors on the board of company
LNSALES	= natural log of total sales
LEV	= ratio of total liabilities to total assets
ROA	= ratio of net income to total assets
BIG4	= dummy variable, 1 if audited by Big 4 audit firms, 0 if otherwise

As prior studies, this study includes board size, firm size, leverage, firm growth and audit quality as control variables in the regression model as these variables have been shown to have impact on earnings quality (Wang, 2006; Jaggi *et al.*, 2007).

3.3 Earnings Quality Variable

To measure earnings quality, this study applies Dechow and Dichev's (2002) accrual quality model (hereafter DD) that captures one aspect of the quality of accruals and earnings. This measure is based on the observation that accruals map into cash flow realizations and regardless of managerial intent, the accrual quality is affected by the measurement error in accruals. The nature of accruals that are frequently based on the assumptions and estimates create estimation errors that need to be corrected in the future.

In the DD approach, the estimated residuals from firm specific regressions of working capital accruals, on past, present, and future cash flow from operation, captures the total accruals estimation error by management and are viewed as an inverse measure of earnings quality. The DD model does not distinguish between intentional and unintentional estimation errors. The approach taken is to assess accruals as a whole as both estimation errors imply a lower quality of earnings.

$$\frac{\Delta TCA_{j,t}}{Assets_{j,t}} = \varphi_{0,j} + \varphi_{1,j} \frac{CFO_{j,t-1}}{Assets_{j,t}} + \varphi_{2,j} \frac{CFO_{j,t}}{Assets_{j,t}} + \varphi_{3,j} \frac{CFO_{j,t+1}}{Assets_{j,t}} + v_{j,t} \ldots\ldots\ldots\ldots\ldots(2)$$

Where:

$\Delta TCA_{j,t}$ = Firm j's total current accruals in year t, = ($\Delta CA_{j,t}$ - $\Delta CL_{j,t}$ - $\Delta Cash_{j,t}$ + $\Delta STDEBT_{j,t}$);

$\Delta CA_{j,t}$ = Firm j's change in current assets between year $t-1$ and year t;

$\Delta CL_{j,t}$ = Firm j's change in current liabilities between year $t-1$ and year t;

$\Delta Cash_{j,t}$ = Firm j's change in cash between year $t-1$ and year t;

$\Delta STDEBT_{j,t}$ = Firm j's change in debt in current liabilities between year $t-1$ and year t;

$Assets_{j,t}$ = Firm j's average total assets in year t and $t-1$; and

$CFO_{j,t}$ = Firm j's net cash flow from operation in year t.

For each firm-year, equation 2 is estimated cross-sectionally for all firms (minimum 8 firms within each industry groups) using rolling 7-year windows. These estimations yield five firm- and year-specific residuals, $v_{j,t}$, $t = t-4,\ldots t$, which form the basis for accrual metric. Accrual Quality $_{j,t} = \sigma (v_{j,t})$, is equal to the standard deviation of firm j's estimated residuals. Larger standard deviations of residuals correspond to poorer accrual quality and vice versa. Following DeFond *et al.* (2007) the standard deviation score is multiplied by -1 so that higher score indicate higher earnings quality (EQ).

4. RESULTS

4.1 DESCRPTIVE STATISTICS

TABLE 1
DESCRIPTIVE STATISTICS FOR DEPENDENT AND INDEPENDENT VARIABLES

	EQ	BIND	BDFINEXP	BDCROSS	BDTENURE	BDSIZE	LNSALES	LEV	ROA	BIG 4
Mean	-0.765	0.414	0.190	0.546	6.6	7.9	19.471	0.487	0.029	0.743
Median	-0.580	0.375	0.167	0.556	5.8	8.0	19.444	0.452	0.034	1.000
Std. Deviation	0.681	0.111	0.110	0.283	4.3	2.0	1.466	0.512	0.151	0.4375
Min	-5.280	0.170	0.000	0.000	0.2	3.0	15.156	0.000	-2.310	0.000
Max	-0.040	0.860	0.600	1.000	29.3	16.0	23.649	7.790	2.010	1.000

As reported in *Table 1*, the mean and median value of earnings quality is -0.765 and -0.580, respectively. In terms of board composition, 87 percent of companies meet the recommendation of the MCCG 2000 to have at least one third of the board comprising independent non-executive directors. The average, 41.4 percent, of the proportion of independent non-executive directors indicates the domination of insiders in the board composition of companies in Malaysia. With respect to financial expertise, each company has at least 1 to 2 members of the board with financial expertise as represented by a median value of 0.167. In terms of board cross-directorship, more than half the board members (54.6 percent) hold additional directorship in other firms. The average length of tenure for independent directors serving in companies in Malaysia is seven years with a maximum value of 29 years.

4.2 CORRELATION ANALYSIS

A Pearson product moment correlation (*r*) was computed to examine the correlation between the independent variables. As illustrated in *Table 2*, board independence, board cross-directorship, board tenure and firm size are significantly related to earnings quality ($\rho < 0.01$). Other independent and controls variables are not correlated with earnings quality. The coefficient of correlation between board independence and earnings quality is however negative, which requires further explanation. With respect

to correlation among variables, the correlation matrix confirms that no multicollinearity exists between the variables since none of the variables correlates above 0.80 or 0.90. All variables have a correlation of less than 0.40.

** Significant at 0.01; *Significant at 0.05

From the analysis conducted, it was found that three out of the four characteristics of board of directors tested in the basic model of this study are significantly associated with earnings quality (*Panel A – Table 3*). The results presented show significant association between board independence (BIND), board governance expertise (BDCROSS) and board firm-specific expertise (BDTENURE) and earnings quality. No association was found between board financial expertise (BDFINEXP) and earnings quality.

Contradictory to the prediction of agency theory, this study finds a significant negative association between board independence (BIND) and earnings quality at 0.05 percent level. It suggests that firms with lower board independence have higher earnings quality. The finding is, however, similar to the earlier paper by Norman *et al.* (2005) and Hashim and Susela (2008b), which report a significant but contrary sign of a relationship between board independence and earnings management for Malaysian companies. Klein *et al.* (2005) raise the issue of the applicability of the agency theory assumptions on the monitoring role by outside directors in countries with a concentrated ownership structure, especially in the hands of family members. As the ownership and control is tighter in family firms, they argue that the demand for outside directors becomes less. Furthermore, Bhagat and Black (2002, p.239) argue that *'if the shift in board composition responds to external pressure, then it may be neither efficient nor an endogenous response to firm characteristics'*. Siregar and Utama

(2008) find that the existence of independent boards do not significantly associated with efficient earnings management in Indonesia as the establishment of the committee is only to comply with the regulations and not for monitoring purposes. As found in this study, most firms in the sample surpassed one-third threshold (as also noted by Abdullah, 2004). Hence, this leads to speculation as to whether the one-third requirement actually works and suggested by Abdullah (2004) although they appear independent they may not be truly independent.

It is found that board governance expertise (BDCROSS) proxy by proportion of directors on the board with directorships in other companies and board firm-specific expertise (BDTENURE) proxy by average number of years of board service of independent non-executive directors are highly significant at 0.05 and 0.01 percent, respectively. Both results show a positive and highly significant relationship between governance expertise and firm-specific expertise with earnings quality. The greater the number of board committee holding additional directorships in other firms enhances the quality of financial reporting of the firm as they gain governance expertise through knowledge they acquire in other firms (Bedard *et al.*, 2004).

Additionally, the results provide strong support of the relationship between firm-specific expertise (BDTENURE) and financial reporting quality, as can be seen in Table 3, which reveals a highly significant relationship between board tenure and earnings quality. Experience as a board member in the same company for a longer period of time helps independent directors gain firm-specific expertise of the company's operation and its other executive directors (Bedard *et al.*, 2004). The increase in the number of years independent directors serve in the firm gives them the ability to effectively monitor the management, which results in a higher quality of financial reporting.

Although governance expertise and firm-specific expertise of boards is found to be highly significant, this study does not find any association between board financial expertise (BDFINEXP) and earnings quality. The finding is, however, consistent with Abdul Rahman and Mohamed Ali (2006) for Malaysian cases. They argue that the establishment of audit committees has yet to achieve its intended goal in Malaysia.

4.4 ADDITIONAL ANALYSES

To ascertain the credibility of initial analysis, two additional tests were carried out; (1) allowing for a possible non-linear relationship between board independence and earnings quality; and (2) using a different proxy to measure board financial expertise.

4.4.1 Alternative Measurement for Board Independence

Thus far, the variable BIND is treated as a linear variable. The result, as shown in *Panel A,* suggests that board independence is significantly associated with earnings quality but in the opposite direction as predicted by the agency theory. It is possible that the relationship between board independence and earnings quality is non-linear. Studies by Bhagat and Black (2002) and Garg (2007) suggest that different proportions of independent directors may differently impact firm performance. For example, Bhagat and Black (2002) suggest that firms may achieve the benefit of firm-specific knowledge when they have a significant number of inside directors – for example 30 percent – but the benefits may be detrimental when there are too many.

Klein (2002) reports that firms with a majority-independent board (i.e. 51 percent or more) produce the highest relationship with abnormal accruals. Although it may be valuable to have a majority of independent directors, Garg (2007) documents that the impact of board independence on firm performance is less when the proportion of board independence is greater than 60 percent. To further investigate this issue, the study adds a squared term for board independence (BIND^2) to the basic model in *Panel A* to test whether the relation between board independence and earnings quality is non-linear. Results reported in *Panel B* indicate that both the estimated coefficient of board independence (BIND) and the square of board independence (BIND^2) are statistically significant at the 5 percent level. Other individual results are not significantly different from the earlier model and all the variables that are significant in *Panel A* remain significant.

Given the estimated values for the BIND and BIND^2 coefficients, the turning point of the relation between board independence and earnings quality is:

Maximisation point = $-b_2/2b_3$ = -5.283 / (2*-6.137) = 43.04% ≈ 43%

The results suggest that as board independence increases the sample firms report higher earnings quality, consistent with the agency theory prediction. However, when board independence reaches beyond 43 percent, a negative association between board independence and earnings quality emerges. In other words, the results suggest that firms with board independence greater than 43 percent will begin to report lower earnings quality.

4.4.2 Alternative Measurement for Board Financial Expertise

The Bursa Malaysia listing requirements require that at least one member of the audit committee is a member of the Malaysian Institute of Accountants. Additionally, the listing requirements stipulate that if they are not a member of the Malaysian Institute of Accountants, they must have at least three years working experience and must have passed the examinations specified in Part 1 of the 1st Schedule of the Accountants Act 1967 or must be a member of one of the associations of accountants as specified in Part 11 of the 1st Schedule of the Accountants Act 1967.

To carry out additional analysis, this study uses a dummy variable to represent firms with a qualified accountant. Consistent with the prior study by Abdul Rahman and Mohamed Ali (2006), the variable board financial expertise is measured using an indicator variable with the value of one if at least one member is a qualified accountant and 0 otherwise. As for the results regarding the board financial expertise as shown in *Panel C*, treating the board financial expertise variable as a dummy variable does not influence earnings quality significantly. Specifically, the results show no significant coefficient with regards to the association between board financial expertise (BDFINEXP_DUM) and earnings quality. This suggests that at least one member of the board being a member of an accounting association or body is not an effective measure to achieve board financial expertise.

5. CONCLUSION, LIMITATIONS AND SUGGESTIONS FOR FUTURE RESEARCH

This paper examines the effect of board independence and board expertise on the financial reporting quality in Malaysia. Using an accrual quality as a measure of earnings quality, this study finds that board expertise is one of the most important determinants of financial reporting quality. Specifically, this study finds a positive significant relationship between additional board directorship and average tenure of

independent directors that capture governance and firm-specific expertise and financial reporting quality. Larger additional directorships of board members and longer average tenure of independent directors enhance the boards monitoring role to produce higher quality financial reporting.

While board governance and firm-specific expertise is found significantly related to earnings quality, this study does not find any support for board financial expertise. Since the revised Code 2007 gives greater concern for audit committees to be all financially literate, future study could examine the effect of having more board members with financial literacy, using a more current sample, to see the effectiveness of this recommendation towards enhancing financial reporting quality. A more refined measure for financial expertise is needed to provide evidence of the relationship between financial expertise and earnings quality. Furthermore, this study only focuses on the board members who are qualified accountants. Each director comes from a different professional category that could add value to the firm (Choi *et al.*, 2007). Perhaps, investigation on the different professional background of directors will provide an interesting avenue for future research.

Corresponding with observations by Barton *et al.* (2004), and a recent empirical study by Garg (2007), this study documents that having a majority of independent directors does not have any impact on earnings quality. In fact, the evidence suggests that the impact of board independence on earnings quality is non-linear. The results of the additional analyses raise concern regarding the appropriateness of policy directives that call for a majority independent directors in countries with a concentrated ownership structure, especially when it is in the hands of family members (Cheung and Chan, 2004; Barton *et al.*, 2004; Klein *et al.*, 2005; Ibrahim and Abdul Samad, 2007). As suggested by Machuga and Teitel (2009), policy makers should consider both firm characteristics and the institutional environments before they implement additional corporate governance reforms especially in countries that are characterized by controlling family ownership and weak legal protection of property rights. Thus, further investigation is needed to assess the effectiveness of the independent directors' monitoring role due to unsatisfactory results from this study.

Session 2.1: Accounting Education

**DATA EXAMINING POSTINGS TO THE DISCUSSION BOARD IN
INTRODUCTORY ACCOUNTING**

Abdel K Halabi, Monash University and University of the Witwatersrand

Abstract

This paper examines discussion board postings by students enrolled in an Introductory
Accounting subject at Monash University. Analysis shows that the total number of
posts increased over a five year period from 2004 – 2008, and that most were made by
Australian on-campus students. The total proportion of students who posted at least one
message on the discussion board was between 14.3 and 20.8 per cent. As there has been
a dearth of research linking accounting education and discussion boards, these results
have a number of implications for university administrators, teaching staff and students.

Key Words*: Accounting Education, Discussion Board, Virtual Learning
Environment's (VLE's).*

Introduction

Universities throughout the world have made large monetary and time investments in
the development and use of Course management tools such as Blackboard and WebCT
(Seale and Mence, 2001). These tools[52] provide an interface that allows for the creation
of Virtual Learning Environment's (VLE's). Today the use of VLE's is commonplace
in many higher education institutions (Love and Fry, 2006), and on the whole students
have positively supported the introduction of VLE's and web based study materials
(Morris and Rippin, 2003).

VLE's act as any other learning environment in that they distribute information and
facilitate learning, communication and collaboration (McKimm, Jollie and Cantillon,
2003). A VLE typically provides functions such as discussion boards, chat rooms,
online assessment, and a range of study materials. VLE's can also be used by staff for
course administration and to track students' use (Mitchell, Dipetta, and Kerr, 2001).

The discussion board is a significant component of VLE's. Discussion boards allow
users to post messages to a shared area or reply to existing messages. Typically,
discussion boards are made up of "folders" or forums containing messages on a
particular subject. Under these folders are "threads", and each thread is a series of
messages about the same topic. Within the thread are "messages" which are individual
contributions to a conversation.

---

[52] According to Altay (2001) WebCT is a 'brand name' and as such is one of 50 or more
competing products that serve as a tool that facilitates the creation of VLE educational
environments.

The primary purpose of this paper is to examine the postings on the discussion board in an introductory accounting subject over a five year period. This is completed through a statistical analysis of all discussion board posts on a semester-by-semester basis. There is a dearth of research on the use of course websites with accounting students (James and Subramaniam 2005; Love and Fry, 2006; Wells, de Lange, and Fieger, 2008; Halabi, de Lange, Hardy and Dyt, 2008), and none that statistically examines discussion board postings. This study will therefore contribute and expand the knowledge related to discussion boards and accounting education, and hopefully prompt further research.

The remainder of this paper proceeds as follows: Firstly the paper examines the features of discussion boards and their contribution to the learning environment. This is followed by a review of the limited research linking accounting education and VLE's and discussion boards. The paper then goes on to describe the particular course and setting, and then presents the aims. The results are then analysed and discussed. Finally the paper concludes with the implications and limitations and outlines some opportunities for further research.

Features of Discussion Boards

In the late 1980's the importance of interactivity in computer mediated communication was noted. Harasim (1989) for example stated that interaction has the greatest potential to impact on learning. In much of the research that follows, the interaction theme is recognized as the most important feature of discussion boards. Garrison, Anderson and Archer (2001) stated that on line learning was important as it created a virtual community of inquiry that allows learners to construct experiences and knowledge through analysis of subject matter, questioning and challenging assumptions. Dennen (2005) also noted that discussion boards allow many opportunities for general interaction and feedback (see also Arbaugh and Durray, 2002). Discussion boards facilitate learner interaction by allowing students to ask questions of the tutor about the any aspect of the course, and enable students to answer one another's questions and develop discussions and debates (Mitchell, Dipetta, and Kerr, 2001).

Marra, Moore and Klimczak, (2004) also stated that instructors and students rely on asynchronous forums to engage one another in ways that potentially promote critical thinking, meaningful problem solving, and knowledge construction. Further advantages of discussion boards are that they do not require the geographical meeting of students, and are not confined to a particular period of time (Marra, Moore and Klimczak, 2004). Discussion boards allow students and tutors to discuss a given topic over an extended period of time.

While there are a number of advantages of discussion boards, Linder and Murphey (2001) noted that concerns involved students not being active participants in discussion forums and interactive sessions. Further, Mitchell, Dipetta, and Kerr, (2001) stated that from an instructor's perspective, managing discussion boards can be difficult and time-consuming.

Accounting Education Research and Discussion Boards

There is little systematic data on accounting students use and perceptions of VLE's. Bryant, Kahle, and Schafer (2005) do discuss the advantages and disadvantages of Blackboard and WebCT functions in the context of distance education only. Love and Fry (2006) noted that research on VLE's is in its infancy and so conducted a phenomenographic study among first year accounting students. Love and Fry (2006) found that students perceived tutors to be using the VLE simply as an 'online textbook', and that the face to face teaching added little value to the VLE. Wells, de Lange, and Fieger (2008) however found that second year students have openly embraced VLE's and support their adoption (see also Halabi, de Lange, Hardy and Dyt, 2008).

In terms of discussion board use, there is very limited accounting education based research (James and Subramaniam, 2005; Halabi, de Lange, Hardy and Dyt, 2008; Wells, de Lange, and Fieger, 2008). Halabi, de Lange, Hardy and Dyt (2008) conducted a survey of introductory accounting students and found those who had used the discussion board felt that "communication and interaction" was the most useful aspect. The majority of students (294 out of a total of 361, or 82 per cent) however had used the VLE to only access information and not for discussion or interaction. Wells, de Lange and Fieger (2008) stated that students appear unwilling to actively participate in two-way online activities.

VLE's at Monash University

VLE's have been widely used in many business related subjects at Monash University since the late 1990's. VLE's grew out of the Gippsland Campus's reliance on off-campus or distance learning (Monash University 2002). Today most subjects at the university offer some VLE to students on any campus and distance education[53].

The Universities' objective of using VLE's is consistent with published research - being to offer flexibility in course presentation and a mode of delivery where teachers and students manage their learning environment (McKimm, Jollie and Cantillon, 2003; Monash University, 2002). VLE's are also consistent with the strategic direction of the university. The "Monash Directions 2025" document states that *"we will demonstrate a deep commitment to internationalism and cross-cultural communication, through our campuses in Australia, Malaysia and South Africa"* (Monash University, 2005).

Introductory Accounting at Monash University

The first introductory accounting subject at Monash University is a core unit in the Bachelor of Business and Commerce. The subject is offered by Monash's three Australian campuses (Gippsland, Berwick, and Peninsula), two international campuses (Malaysia and South Africa), and through distance education.

In the three Australian and two international campuses, the subject is taught face-to-face. These students receive a weekly two hour lecture and one hour tutorial. Distance

---

[53] Monash University has six Australian campuses and one in Malaysia and South Africa.

education students are supplied with specifically produced printed materials with instructor contact available through telephone, email and fax. All students receive the same curriculum, undertake the same assessment tasks (including examinations) and are assessed by the same criteria (Monash University, 2002).

One Chief Examiner heads the subject, and individual lecturers are responsible for the administration and teaching on that campus. All teaching staff have input into the assessments, marking guides and final examination, and also moderate assignments and examinations from all locations. This helps to ensure compliance to the marking scheme and consistency in the final marks.

The first VLE for the subject was created in 1998 through the Webface platform. This was a straightforward environment that provided basic course information and study materials to distance education students only. The printed materials that were sent to distance education students for example were also placed on Webface as were memos regarding course announcements (these were also distributed by mail). There was no opportunity for interaction with other students or the teaching staff, as the discussion board was not operational. The VLE duplicated much of the printed materials already sent to students.

The migration from Webface to WebCT in 2001 brought greater opportunities for interactivity and creativity. Discussion boards were introduced, as were some on-line chat facilities. The VLE was extended to other on campus students at the Gippsland campus in, 2001 and to other Australian campuses in 2002. In 2004 the VLE was extended to Monash's International campuses.

Today all students (irrespective of mode or campus location) have the same subject VLE designed through Blackboard. All study material is provided including distance education printed materials; weekly lecture notes; lecture exercises and solutions; tutorial questions and solutions, and past examinations and solutions. A calendar of events is also included. The VLE provides links to sites such as those assisting with the presentation and preparation of assignments, professional accounting associations, university regulations, and staff email directories. In terms of interaction, there is a discussion board and an on-line chat facility that all students can access. These interactive features mean that students can communicate with each other irrespective of their geographical location.

The VLE for the subject is maintained by the Chief Examiner with some assistance from the universities' technical support. The Chief Examiner uploads relevant notices, the weekly lecture material, solutions to tutorials questions, and manages the discussion board. Teaching staff on individual campuses are given "teacher/tutor" access to enable them to engage in discussion and post notices relevant to their individual campuses.

Aims of the Present Study

Initial evaluation of discussion boards focused on descriptive statistics regarding the number of postings, and participation rates of students (see de Laat, 2001). Later research analysed the content of online discussion. Marra, Moore and Klimczak (2004)

for example stated that online postings can be analysed in a number of ways including social, interactive, metacognitve (reasoning), and cognitive groups (elementary clarification, in depth clarification, inference, judgment and strategies).   Burnett (2000) stated that the interactive dimension of discussion board posts could be analysed into hostile or collaborative. Finally Marra, Moore and Klimczak, (2004) reported that discussion posts could be analysed in forty different ways including relevance, justification, novelty, ambiguity each with a plus or minus code to indicate whether the comment was negative or positive.

Prior research that has examined online discussions by content analysis has mainly focused on classes with small numbers, and over a limited time period.   Marra, Moore and Klimczak (2004) for instance analysed the discussion board for 21 students enrolled in a graduate course involving 53 postings.

Because of the large numbers of students involved in the Introductory Accounting subject, and the potential for a large number of discussion board posts to be made, a content analysis is beyond the scope of the present study. As there has very little prior research examining discussion boards in accounting education, this study will provide statistical data on the numbers of posts made per semester over a five year period, and examine the participation rates of students by campus.   The main question to examine is while VLE's have become more common, has this led to an increase in the number of discussion board posts and participation amongst students over a five year period? Analysis will be conducted on total student postings according to folders, by campus, and the number of students who posted messages.

Data
Data for this study was obtained from analysing the Introductory Accounting subject discussion board postings at the end of each semester beginning from semester 1, 2004 to semester 2, 2008[54]. The subject is offered in both semesters with enrolments usually larger in the first semester. The results are analysed by separate semesters.

Results and Discussion
Five categories (or folders) are used to analyse the postings. The folder titled "General Discussion" concerned items of a very general nature that related to the subject, and included course and administrative arrangements. Folders "Ass 1" and "Ass 2" concerned postings specifically related to the first and second assignments[55]. The folder "Exam" related to information on the final examination including types of questions and topics, structure of the paper.   Finally the discussion board included twelve folders for the weekly topics of the course. These were collapsed into one folder titled "weekly topics".

---

[54] The subjects had not changed in content over the time period. The chief examiner remained the same, as did the textbook (a later edition of the text book was used which involved minor changes such as name changes to the accounting reports). Finally, all assignments and examinations were different but based on similar concepts.
[55] There were two assignments set in the subject. The first was worth 12% of the total mark, while the second was worth 18%.

Table 1 highlights the total posts made by students according to "folders" from semester 1 2004 to semester 2, 2008. The total number of students enrolled is also provided, and the total number of posts per student is calculated.

	Number of Posts

Total Posts Per Student	0.33	0.49	0.51	0.64	0.51	0.45	0.55	0.67	0.78	0.63

Table 1: Discussion board posts made by all students according to folders

Table 1 shows that the total number of discussion board posts over both semesters increased from 2004 – 2007 and then fell away slightly in 2008. The most posts were made to the "Ass 2" folder except in semester 2, 2007. The second assignment was an accounting manual practice set involving the accounting and bookkeeping process, and the large number of posts could be due to any of the following reasons: The assignment was lengthy; the assignment was worth 18% of the final assessment; students normally required assistance throughout the various stages but particularly in the beginning; students wanted to check their progress and balances at different stages; there was over six weeks to complete the project. While the examination was worth significantly more than the second assignment (70% of final assessment) it did not make up a large part of the discussion. This was primarily because a detailed memo was supplied to all students outlining the format of the paper and the types of questions to expect. The discussion board was also closed on the day of the examination.

Table 1 also analysed the number of posts by the total number of students enrolled. The results show that the number of posts as a proportion of the total student population has also increased over both semesters from 2004 to 2007, and then decreased in 2008. Interestingly, the total number of posts per student was always higher in the second semester, even though the number of students enrolled was smaller. The second semester cohort usually included a number of students who were failures from prior semesters, and the repeating students may have made more postings than usual to clarify certain points. Students in the second semester may also have felt that the smaller number of students allowed greater opportunities for interaction.

The next analysis examined the number of discussion board posts by the campus in which students were enrolled. The three Australian campuses were collapsed into one group ("Internal Australia"). The other campus/student groups were from Malaysia, South Africa, and Distance education. Results on the total number of posts per campus/student group and posts per student are presented in Table 2.

Campus/Student Group	Total Number of Posts By Campus									
	Semester 1					Semester 2				
	2004	2005	2006	2007	2008	2004	2005	2006	2007	2008

Total	0.33	0.49	0.51	0.64	0.51	0.45	0.55	0.67	0.78	0.63

Table 2: Discussion board posts analysed by Campus

Table 2 shows that the most number of posts in all semesters was made by "Internal Australia" students followed by those enrolled through distance education. The students from South Africa used the discussion board the least, and in some cases not at all. Analysis revealed that the internet was very slow in South Africa, and the campus used an alternative means of supplying study materials, which did not involve a discussion board facility. The Malaysian cohort also rarely used the discussion board.

Table 2 shows that the total number of posts by the "Internal Australia" students and "Distance Education" increased from 2004 – 2007, but fell away in 2008. Discussion board postings have however increased over the analysis period for the Malaysian and South African groups. This perhaps highlights that the VLE is becoming more accepted by students on all campuses, and maybe some evidence that the university is achieving its goal of "internationalism and cross-cultural communication" (Monash University, 2007).

As a proportion of students enrolled, Table 2 also shows that the most posts were made by "Internal Australia" students again followed by those enrolled in "Distance Education". In similar results to Table 1, the proportion of postings per student was always higher in the second semester compared to the first for both "Internal Australia"

students and "Distance Education".   This was however not the case for Malaysian and South African students.

Finally, analysis was conducted on the number of students actually posting to the discussion board. Table 3 shows the number of posts made by different students, and the percentage of students making posts. For interest, the table also highlights the highest number of posts by a single student during that semester.

| | Total Number of Posts by Different Students | | | | | | | | | |
| | Semester 1 | | | | | Semester 2 | | | | |
	2004	2005	2006	2007	2008	2004	2005	2006	2007	2008

Most Posts by a Student	15	32	36	45	22	27	42	30	44	22

Table 3: Total Number of Posts by Different Students

Table 3 shows that the total number of students making at least one post on the discussion board has increased from 2004 – 2008 in both semesters. Overall the percentage of students who have made at least one post has been between 14.3 per cent (semester 1, 2006) and 20.8 per cent (semester 2, 2006). The percentage of students making at least one post on the discussion board was generally more in the second semester than the first. Table 3 also shows the most number of posts made by a particular student, which has varied between 15 (semester 1, 2004), and 44 (semester 2, 2007).

Conclusion

This study has provided statistical data on postings to the discussion board over a five year period for an Introductory Accounting subject. Results showed that the total number of posts on the discussion board increased from 2004 to 2007 however fell in 2008 (Table 1). The most activity on the discussion board was from Internal Australian students, followed by Distance Education. Although there was very little activity from the international campuses of Monash, there is evidence that this is increasing (Table 2). Finally the results show that the percentage of students making posts to the discussion board was between 14.3 per cent and 20.8 per cent over the five year period (Table 3).

The results have a number of implications for administrators of universities, staff and students. For administrators, the results highlight that while great investments have been made in VLE's, and students are generally positive about the change (Seale and Mence, 2001; Love and Fry, 2006; Morris and Rippin, 2003), the discussion board only

attracts between 14 and 20 per cent of students to post questions or reply to answers. As one of the major advantages of VLE's is to increase access, it would seem that the discussion board may not be achieving this, if indeed access is measured by number of students posting.

The results also have implications for staff. While the total number of posts to the discussion board has increased, the majority of students do not participate. Prior research has shown those who use the discussion board said that interactivity was the greatest benefit (see Halabi de Lange, Hardy and Dyt, 2008). Therefore staff should try to involve as many students as possible in discussions and remind them of the benefits of participation (as they would a face-to-face class). The discussion board in the present study was set up to be essentially "student based", and staff only answered questions when specifically requested, or when students were incorrect. This was the decision of the staff involved being - to maintain the discussion board as a student centred forum with little input from staff. Teaching staff may be able to make more students active participants in the discussion forums by prompting questions, or raising issues. Students could also be given a mark for their participation in the discussion board (see Marra, Moore and Klimczak, 2004), though not all students are comfortable with using discussion boards, and staff must be aware of this before any assessment grade can be determined (Linder and Murphey, 2001).

A further implication for teaching staff may be specifically directed for those who work on universities with a number of campuses - whether these are within their country or internationally. A feature of the discussion board is that it does not require the geographical meeting of students (Marra, Moore and Klimczak, 2004), Staff should be encouraged to make all students from locations involved in the discussion board. Accounting as an "international" subject is well placed to allow students from all over the world to discuss similar issues. Perhaps an assignment may be set where students examine accounting reports of different countries, with teacher promoted discussions comparing accounting similarities and differences across national boundaries. Further, students from various locations could be grouped together to work on assignments and discussion boards used as a means of communication.

Finally the results have implications for students. All students need to be made aware of the advantages of discussion boards - that is that they can facilitate learner interaction promote critical thinking, problem solving and knowledge construction (Marra, Moore and Klimczak, 2004; Garrison, Anderson and Archer, 2001). This may promote more students to post to the board. Involving students in discussion forums can be likened to discussing issues in class, and students need to be able to see the similarities and advantages.

There a number of limitations for this study, however these provide many opportunities for further research. The study was only restricted to five years data and conducted at one university. The results therefore can not be generalized beyond that university or the sample size. The results from other universities would add to the dearth of research in this area.

The present study ignored "discussion board usage" - or the actual number of students who had read postings. Anecdotal evidence would suggest that many students use the discussion board and read the posts. Facilities in Blackboard and WebCT enable the collection of information on student usage of the entire VLE (Mitchell, Dipetta, and Kerr, 2001), however what would be more applicable in this instance would be a specific measure of the time spent reading or using the discussion board. This is an issue for administrators to deal with, and perhaps a direction of further advancement of the Blackboard functions which can lead to further research.

This research used statistical data to measure postings to the discussion board. There was no analysis of the content. Valid tools exist for assessing discussion forum content (see Marra, Moore and Klimczak, 2004) and accounting educational research could move into this area. Because of the large number of posts in the Introductory accounting subject and the considerable time taken to analyse the posts, research in this area may be beyond the beginning subject. Rather it may be best to examine the content of discussion board post to smaller student enrolled subjects, or over certain time periods (Marra, Moore and Klimczak, 2004).

The research did not examine the performance of students who have used the discussion board against those that did not, and this could be another direction of further research. Marra, Moore and Klimczak, (2004) stated that discussion boards may promote critical thinking, and knowledge construction (see also Garrison, Anderson and Archer, 2001). This could be tested by analysing the end of semester marks. More information would need to be collected to properly do a study in this area (for example prior accounting knowledge, gender, location, motivation), and these variables would need to be controlled.

Even though some limitations exist, this study has provided important knowledge on the use of discussion boards by introductory accounting students, particularly as this is an under-researched area. There still remains many issues that warrants further research. The results of this study are important as they have implications for university administrators, academic staff and students.

INVESTIGATION OF IMPORTANCE ETHICS EDUCATION IN ACCOUNTING CURRICULUM

Saeed Jabbarzade Kangar lui, Scientific broad IAU of Urmia
Akbar Pourreza soltan ahmadi, Scientific broad IAU of Salmas

Abstract

Accounting students become practitioners facing ethical decision making challenges that can be subject to various interpretations; hence, the profession in concerned with the appropriateness of their decisions. On the other hand an argument for the existence of accounting education in the university and the importance of a ethical foundation for business ethics is presented to justify its place in the university. The accounting profession has responded to this concern by establishing cods of professional conduct and using influence to promote ethics education. It is argued that accounting education is consistent with the nature and purpose of higher education. To perform his or her social function the accountant needs both technical expertise and moral expertise. A central organizing principle is needed to ensure that the accountant develops both types of expertise. This organizing principle is integrity. The integration of ethics into the accounting curriculum entails developing technical expertise in an educational environment which encourages reflective thinking about the role of the profession, the exercise of moral reasoning and integrity to exercise one's personal moral responsibility. This paper concludes with a model for ethics integration and points that accounting students should be required to have a class in ethics as part of their collage curriculum.

Introduction

As the conscience of business, professional accountants often find themselves facing competing obligations. It is arguable that they have obligations to shareholders, creditors, employees, suppliers, the government, the accounting profession and the

public at large. In other words, their obligations go beyond their immediate client. The work of the accountant can affect the lives of many people. This is why ethics is so important to the education of professional accountants.

The main objective of this paper is to develop a model for integration ethics into the accounting curriculum. Several related sub questions will be addressed in the process why is ethics in accounting an important problem?

What is the nature and purpose of higher education and place of the study of business with in?

How can the principles of higher education be applied to accounting?

What is the organizing principle for integrating ethics into the accounting curriculum?

Each of questions mentioned above are explained in continue. In general this paper takes a holistic approach to the problem of integrating ethics into accounting education. The moral point of view for those who teach accounting is that we aim at developing a curriculum which will help graduates to become morally autonomous technically competent, caring member of society. The pillar upon which this goal resets is that of integrity: integrity in terms of curriculum content, the setting in which learning takes place, and the development of the moral virtue of integrity itself.

The importance of ethics in the accounting profession

Although ethics has been an issue in the accounting profession for years, it has currently become a widely discussed and debated topic. The seriousness of the general problem of the role of ethics in accounting and business education will become apparent in examining some of the key ethical problems faced by accounting professionals. A review will be presented of what is currently being done by universities and by the accounting profession to help raise ethical standards.

Ethics in the accounting profession:

Ethics and professionalism are intertwined. Professionalism implies trust and trust is an ethical concept. Integrity is expected of all professionals, including doctors, lawyers and accountants. However, the integrity and ethical behavior of accountants is particularly scrutinized because of their responsibility and accountability to the public." Of all the groups of professions which are closely allied with business, there is none in which the practitioners is under a greater ethical obligation to persons who are not his immediate clients"(may,1995).

However, because of reports of unethical behavior in the business community, the accounting profession has come under increasing criticism, and public confidence in the profession has been shaken. Without this confidence the economic system could be in trouble.

Ethics in accounting education:

Due to highly publicized revelations of unethical practices in the business community, universities and educators are being pressured to teach business ethics. In general, there is widespread belief that students are not receiving adequate exposure to ethical concerns before entering the work force. Several questions have been raised with respect to how business ethics material should be though, and there is concern over whether it is even possible that ethics can be taught. In outlining the future scope and content of accounting education, the issue of ethics is recognized as being important to the ever changing profession. professional accounting education must not only emphasize the needed skills and knowledge, it must also instill the ethical standards and the commitment of a professional the business and accounting curricula should emphasize ethical values by integrating their development with the acquisition of knowledge and skills to help prevent, detect and deter fraudulent financial reporting. Business schools should encourage business and accounting faculty to develop their own personal competence as well as classroom materials for conveying information,

skills and ethical values that can help prevent, detect and deter fraudulent financial reporting.

Extent of ethics in accounting education:

Although the accounting profession has been only partially successful in making ethics an explicit of the curriculum, ethics has become a major concern and all major accounting associations have cods of ethics and standards and discipline committees to help enforce them. For example IAFC code of ethics consist of principles of integrity, objectivity, professional competence and due care, confidentiality and professional behavior, AICPA code of ethics consist of principles of responsibilities, the public interest, integrity, objectivity and independence.

The evidence shows, however, that accounting ethics is still not seen as a separate area of study. Although ethics is addressed through a variety of sources and there is some coverage of ethics in auditing and other accounting courses, this is of a limited nature because of the recent recommendations stressing a need to increase coverage of ethics in the accounting curriculum more effort is required to ensure that it gets done effectively.

Ethical frameworks:

There are well established frameworks of ethical behavior that are used to direct human action and to assist in resolving ethical dilemmas. Frameworks provide theories to enhance moral reasoning and strengthen our ability to make decisions on what can and cannot be justified in terms of both business practice and educational activity. The frameworks are well known in the literature. However, a brief review will summarize the main ones which appear in the accounting ethics literature 1) utilitarianism 2) deontologism and 3) justice.

Utilitarianism:

Utilitarianism is a teleological ethical system. That is, one which bases obligation and rights on values which hold that an action is right if it brings about good consequences. Teleological theories maintain that the morality of an action depends on the non moral consequences which result from the action. Two teleological theories which dominate the literature are egoism and utilitarianism. Egoism is concerned with what are the best of self, while utilitarianism is concerned with the best consequences for all or for the greatest number.

There are two branches of utilitarianism, act and rule utilitarianism. With act utilitarianism an act is right if it maximizes utility by producing the greatest balance of good over evil for everyone. According to act utilitarianism, moral rules such as " do not steal " or " do not lie " serve only as rules of thumb which may be altered in the light of particular circumstances so that there can be the greatest good for the greatest number.

As a practical matter, utilitarianism seems quite attractive the idea of providing the greatest good to the greatest number can be intuitively appealing. For example, when judging the effectiveness of an education program, utilitarianism provides a convenient rationale. Whit respect to curriculum content, utilitarians would judge educational activities according to how much pleasure or happiness is associated with the educational activity.

Deontologism:

Theories of rights are known as deontologism, from the Greek word deon, meaning duty. Deontologists hold that right action ought not to depend on its consequences. Deontology is the study of moral commitment. According to this framework, an act or rule brings into existence inherent value sprouting moral principle and a person has a moral duty to perform the right action regardless of the consequences. The deontological dimension of education is respect to autonomy. This suggests that the

curriculum be designed to help individuals develop critical thinking skills. This dimension can serve as an adequate basis for the ethical curriculum. The emphasis on autonomy and critical thinking however, must conform to the concept of integrity. Without integrity critical thinking can manifest itself in skilful but selfish manipulation designed to serve self interest or the vested interest of some groups at the expense of others.

Justice:

Guided by concepts such as equity, fairness and impartiality theories of justice go back as far as Aristotle and Plato. In business, issues of justice arise whenever there are conflicts of interest among stakeholders such as consumers, managers, shareholders and others. A major contribution to the issue of justice has come form the work of john Rawls(1971). According to Rawls, the concept of distributive justice (that equals should be treated equally and unequal unequally) must be maintained to prevent social unrest. Ethical frameworks can be a useful vehicle for sensitizing accounting students to ethical issues and giving them the tools to analyze what may be their intuitive positions, or at least reasoned out positions, on any given ethical problem. Ethical frameworks are helpful in determining the basic ethical principles at work in business and in applying ethical principles to ethical problems.

Goals of teaching business ethics:

At least five goals of moral education have been identified in the literature. Callagan (1980) has suggested the following: 1) stimulating the moral imagination 2) recognizing ethical issues 3) developing analytical skills 4) eliciting a sense of moral obligation and personal responsibility and 5) tolerating and resisting disagreement and ambiguity. Each of these goals will now be briefly examined for their relevance as goals for integrating ethics into accounting education.

426

Callagan suggests that ethics education should be more than an intellectual exercise: that it should stimulate the feelings and imagination of students. Students need to be taught that we live our lives in a web of human relationship such that moral actions can cause pain or joy to others. Callagan does not mention accounting education or business practice, but this web of moral relationships is a very appropriate description. Actions by managers can powerfully influence the lives of those under their control. Callagan's second goal, developing the ability to recognize moral issues is closely related to the first goal. It means, however, going beyond feelings and emotional responses to rationally sort out emotionally charged reactions.

The development of analytical skills is necessary in order to make a proper moral evaluation. Callagan recognizes the complex problem in dealing with concepts such as "justice", "right" or "good", but stresses the importance of coherence and consistency as minimal goals to development of analytical skills.

The goal of eliciting a sense of moral obligation and responsibility is one over which a teacher may have the leat influence. The idea that people must be free to make moral choices and be responsible to others for their choices is fundamental to the nation of ethics. If students of accounting lack this feeling of moral responsibility ethics education may not have much influence.

Callagan argues that students need to learn to tolerate the disagreements and to be prepared to accept the inevitable ambiguities in attempting to examine ethical problems.

callagan's goals seem to provide a framework for bringing business ethics into the accounting curriculum. For accounting education a sixth goal, however, should be added to reflect the additional responsibility of professionals. This goals is to instill a hightened sense of moral and social responsibility that encompasses critical inquiry. Because of the special power and privilege which society bestows upon professionals, society has a right to expect that professionals acquire a hightened sense of moral and

427

social responsibility that would ensure that integrity is exercised in carring out professional functions. This would entail a strong and consistent commitment to do what is right and not to abuse their positions of trust or be unduly influenced by powerful individuals or interest groups.

Ethics in the curriculum

Business schools in U.S use several approaches to teaching ethics in the curriculum. Some schools have a required ethics course, either in the liberal arts core or in the business core. These stand alone ethics courses may be taught by professors trained in philosophy, religions studies, or various business disciplines. One possible problem with a stand alone ethics course is that students may not apply what they learn in the ethics course to business issues. For example, several accounting courses require students to incorporate ethical issues into the business decision model this gives business students an opportunity to apply ethical principles in the accounting and other business classes they take. While student's ethical values may be substantially formed by the time they get to college, they nonetheless can learn to include their values in business decisions. Accordingly, accounting and business classes require students to look beyond the bottom line, and include ethical issues in their business decision models. In summary, the model for integrating ethics into the accounting curriculum is as follows:

1) Devote half a semester of the introduction to business course to general business ethics.

2) Integrate ethics into each and every accounting course throughout the curriculum.

3) Develop a capstone course at the senior level which deals with complex issues of business social responsibility and professional responsibility.

This approach to ethics integration provides the student with both brand and specific exposure to business and accounting ethics. Society will benefit from educated individuals with high ethical reasoning ability who are sensitized to ethical issues and

who have developed the habit of careful reflection. This combination of ethical reasoning, sensitization, and reflective thought are nation the seeds for building integrity, the central organization principle of ethical behavior.

Suggested topics of ethics courses

1) Integrity

2) Honesty

3) Ethical reasoning

4) Making correct choices under pressure

5) Independence

6) Objectivity

7) Impartiality

8) Confidentiality

9) Professional institutes codes of conduct

10) Moral exemplars

11) State codes of conduct

12) Financial markets rules

13) Autonomy

14) Discretion

15) Ethical theory

16) Self determination

17) Moral development justice

18) Caring and compassion

19) Human rights

20) Business low

21) Self sacrifice

22) Kindness

23) Diversity

24) Environmentalism

25) Philanthropy

Conclusion:

Ethics is a critical issue in accounting practice, and consequently, to accounting education. A heightened public concern regarding business ethics as well as a declining influence of social institutions has increased the role educators must play in forming student's ethical attitudes and beliefs. Students themselves have indicated that they are looking for and need ethical and moral direction. On the other hand, fraud will not be eliminated, regardless of how well business schools do in teaching ethics. But ethics can be an important part of the business curriculum, and students can learn that ethics matters in business decisions. A theme throughout this paper has been that a fundamental role of the university is to produce educated people and the moral integrity is central to being an educated person. Accounting education provides socially useful knowledge. When the accounting curriculum is taught in an environment that encourages reflective thinking about the social responsibility of accounting professionals, and promotes integrity as the central organizing principle for ethical behavior in business, accounting education legitimately belongs in the university.

THE USE OF REFLECTIVE LEARNING JOURNALS AS A LEARNING AND ASSESSMENT METHOD WITHIN AN ENTRY LEVEL TERTIARY ACCOUNTING PAPER

Louise MacKenzie, University of Otago
(First Draft – please do not quote)

Abstract

This paper outlines and evaluates the use of reflective learning journals as both a learning and assessment technique in an entry-level accounting paper.

In 2003 a Tertiary Institution in the North Island of New Zealand (TI) undertook an internal Teaching, Learning and Assessment (TLA) Pilot Programme. This internal initiative was aimed at introducing innovative teaching and assessment practices which assisted a transition from content-focussed, lecturer-centred passive learning to more student-centred reflective learning.

There was also a need to promote the development of communication and academic competencies. Interpersonal and communicating skills are widely recognised by the accounting profession as critical to successful practice and are recognised by the International Federation of Accountants as a key component of its Professional Skills standards for accountants.

One of the outcomes of the TLA pilot programme was the implementation, within the entry-level accounting paper, of a compulsory Professional Skills component utilising specialist language tutors and requiring the students to complete individual Reflective Learning Journals based on their accounting course work. The TLA programme was implemented in Semester One, 2004.

Reflective Learning Journals are not usually considered by tertiary educators as a tool in the teaching of accounting. However, depending on the method of implementation, they can provide many benefits, both anticipated and unanticipated.

This paper outlines and discusses the implementation procedure of the Reflective Learning Journal assessment and summarises the final feedback from students and staff. It concludes that Reflective Learning Journals have a role to play in an entry level accounting course, and gives suggestions on how to successfully implement this method of assessment.

KEY WORDS: Reflective learning journal, reflective learning, communication skills.

Introduction

Over the last few years there has been a call for improvement in Accounting Education. Accounting educators were accused of teaching programmes based on the rote learning of rules and procedures. They taught process, not a body of knowledge. In 1988 the managing partners of the then big 8 accounting firms concluded that upcoming accounting graduates "lacked the skills and abilities to succeed in the competitive environment of the 1990's and 21st century" (American Accounting

Association, 2003). They issued 'The Big 8 White Paper' which stated "the focus should be on developing analytical and conceptual thinking vs memorising".

Subsequently, in 1989, the American Accounting Association appointed the Accounting Education Change Commission, whose brief was to be a catalyst for change in accounting education programmes.

Albrecht and Sack (2000) write that 'current accounting education is thought to be broken, outdated and in the need of change' because it does not equip graduates with the skills required by business employers. The focus of most accounting courses leaves little time for developing the skills that most employers seek (Diller-Haas, 2004).

In the modern, globalised economy the skills that business employers require from business graduates are 'soft, or 'transferable' skills. The recently released National Commission on Writing's report (2003) states that business graduates need to be equipped to meet the writing demands of the workplace. Interpersonal and communicating skills are widely recognised by the accounting profession as critical to successful practice and are recognised by the International Federation of Accountants as a key component of its Professional Skills standards for accountants.

In 2003, the Business Faculty at a Tertiary Institution (TIBF) in the North Island of New Zealand undertook an internal Teaching, Learning and Assessment (TLA) Pilot Programme. This initiative was aimed at introducing innovative teaching and assessment practices which:

 a) better met and developed the student capabilities inherent in the relevant graduate profile;

433

b)   increased the level of independent learning while decreasing passive learning;

c)   increased, or maintained, security of assessment.

This initiative was aimed at introducing innovative teaching and assessment practices which assisted a transition from content-focussed, lecturer-centred passive learning to more student-centred reflective learning, thereby promoting the development of communication and academic competencies. Within the TIBF, the objectives of the TLA pilot also served to better meet the International Federation of Accountants Professional Skills standards for accountants.

NZ100 Accounting Principles (NZ100), a compulsory national New Zealand Diploma in Business (NZDipBus) course, was one of the papers chosen to participate in this programme. As part of the subsequent changes and developments to the assessment for this paper a decision was made to introduce a Reflective Learning Journal as an assessable activity.

What is Reflective Learning?

The academic study of accounting requires the need for many modes of cognition. Reflection is particularly useful as it can help students turn classroom experience into actual learning and understanding.

"Learning = Programmed Knowledge + Questioning Insight

(Revans (1983)

The term 'Reflection' can mean a number of things. Schon (1983, 1987) believes that reflection is something that occurs in action or during action rather than after the action is completed.

Brown & McCartney put forward a comparison of Reflection ON Action and Reflection IN Action, as in Table One below:

Table One: Types of Reflection (source: Brown & McCartney, 2002, p.127)

Reflection On Action. Time Line: Past	Reflection In Action. Time Line: Present
This refers to the process of making sense of an action after it has occurred and possibly learning something form the experience which extends one's knowledge base. It may affect the action being reflected upon because that has already passed.	This process: ▪ is, at least in some measure, conscious, although it need not occur in the medium of words ▪ has a critical function, questioning the assumptional structure of knowing in action (the type of know how we reveal when we act) ▪ gives rise to on-the-spot experiment

Because the TIBF were wanting students to provide evidence from, comment and reflect on their course work and because NZ100 is an entry-level paper, an assessment activity was designed with a focus on Reflection On Action (Brown & McCartney, 2002). In order to meet the objectives of both the TLA programme and the paper, the assessment activity was to be a Reflective Learning Journal.

A Reflective Learning Journal is more than just a log, recording activities or events. It is also not a personal diary. A Reflective Learning Journal is a systematic way of documenting and collecting information for reflection and self-analysis (Kerka, 1996). The learning journal can be a powerful tool for developing student confidence and cognitive ability (O'Rourke, 1998).

What results do others claim?

There has been a great deal of research on Reflective Learning, and Reflective Learning Journals, in disciplines other than accounting. Extensive literature and research exists on the use of Reflective Learning Journals in, for example, Marketing, Law, Economics, Geography, Nursing, Teacher training.

In studying the journals of student teachers, Surbeck, Han and Moyer (1991) found that 'using the journals takes time, but assists students in becoming better thinkers'. In a pilot of learning journals with undergraduate English students it was found they were 'forced to think harder and in more original ways about the content of the module (O'Rourke, 1998). Holt (1994) found that when used with adult learners, Reflective Learning Journals stimulated cognitive activities such as observation, speculation, doubt, questioning, self-awareness, problem stating and problem solving. Baltensperger (1987) claims that students who completed Reflective Leaning Journals in his Economic Geography course benefited tremendously: they were better able to focus on the concepts presented, they were considerably more advanced in their comprehension and recall, and they expressed enthusiasm about their learning experience.

Through the completion of a Reflective Learning Journal students learn to connect the abstract and the concrete, and develop thinking skills and strategies they need for higher-level papers (Schatzberg-Smith 1989). The keeping of Reflective Learning Journals has been found to 'reveal thought process and mental habits, aids memory, and provides a context for growth (Schneider 1994).

The current research and literature on Reflective Learning Journals show that keeping a journal is not simply a vehicle for students to demonstrate what they know; it is a vehicle to help students understand what they know.

The TIBF felt it was possible to apply the benefits of Reflective Learning Journals to Accounting, in particular to the NZ100 entry level accounting course

Implementation

"Reflecting is a skill which has to be learnt and practised" (Robles, 1998)

The TIBF were aware of the need not just to get students to write, but to get them to reflect. Therefore there was a necessity to provide a strong framework and guidelines if the students were to develop reflective practices (Woodward and Sinclair, 1998).

They were also aware that "Assessments of student writing must go beyond multiple choice, machine-scorable items. Assessment should provide students with adequate time to write and should require students to actually create a piece of prose" (National Commission on Writing, 2003).

In addition to the weekly lectures and subject tutorials, students were allocated an additional compulsory one hour Professional Skills Development (PSD) tutorial. These were run by qualified language tutors on secondment to the TI's Business Faculty. Each PSD tutorial had a maximum of 20 students, thereby allowing the PSD tutor time to work with each student as required. The language tutors worked to a brief provided by the NZ100 Course Co-ordinator.

The Reflective Learning Journal was an assessable assignment, with the completion of the Journal to occur at the PSD tutorial. Attendance at the PSD tutorials was therefore compulsory for all students and formed part of the requirements for assessment completion. A pre-determined weekly journal topic was completed during the tutorials, under the guidance and with the assistance of the PSD tutor. The Journal was required to be hand-written.

At the start of the semester students were provided with a full assignment brief (refer Appendix) explaining the aims and process of the Reflective Learning Journal assessment activity. The assignment brief also included some guidelines as to undertaking and completing the Reflective Learning Journal. The topics for each week of the semester were also provided. This is in keeping with Hunter & O'Rourke (1996) who found that 'simply telling students to keep a learning journal does not work. They need to know why they are being asked to do it, and how to do it or else … the journals become either a mere record of events, or an opportunity for emotional splurges'

Topics required students to give their own views on something, not learn and repeat text. For example, if the weekly topic was "in your own words, comment on what you see as the purpose of the statement of financial position" a student was fully entitled to write that they thought it was a waste of time, provided they justified their comments. Students were encouraged to write what they thought, not what they thought their lecturers wanted to hear.

All topics were based on assessable topics from the NZDipBus NZ100 Accounting Principles national prescription. This required students to provide evidence from their course work, which ensured their reflection was focussed on their actual experience of the course. This is in keeping with O'Rourke (1998).

438

Assessment

One of the biggest perceived difficulties with written work, reflective written work in particular, is how to assess. Assessment issues include how to determine what criteria to assess against, and how to determine the authenticity of the work being assessed.

The Reflective Learning Journals were handed in to the PSD tutors at the PSD tutorials. Tutors then passed the Journals on to the lecturers for marking, lecturers marked the journals and handed them back to students at the next lecture.

Students were marked on specific achievement-based criteria, which formed part of the initial assignment brief that was handed to students at the start of the semester. The full criteria are in the Appendix; a summary is as follows:

- Attendance at PSD tutorial

- Meeting every hand-in (5 throughout the 13 week semester. This ensured completion was regular, and not the night before the last day of the semester)

- Evidence of maintenance of a weekly learning journal that covers the required topic of the week

- Presentation and readability

- Provision of a well-structured and well-laid out document

- Logical, fluent, succinct and mainly correct grammar and spelling

Achievement-based criteria were chosen because it gave students the incentive for improvement. As final marks were awarded on the highest level of achievement attained, students were encouraged to improve their content and presentation.

The issue of the authenticity of the work being assessed was dealt with by having students manually complete their Reflective Learning Journals in the PSD tutorials. Any student who completed their work on the computer, or who completed their work at home and only attended PSD tutorials to hand their journal in, did not receive any marks. This was made clear to students within the written assessment criteria.

Evaluation of Results

Qualitative results are available from feedback from the students themselves, from the writings in the Reflective Learning Journals, and from the comments from the markers of the final examination. Quantitative results are available from the tracking the marks from the final examination over the last two semesters prior to journal implementation, and the semester of implementation.

With regards qualitative results, the following Reflective Learning Journal excerpts illustrate positive student feedback:

"It helped me make sense of the whole course, and how it all fitted in. I wish we'd had the journal last time I did the course."

"I have learnt a lot from doing the journal and see now how I can apply to what I have learnt to my work"

"Teachers at school always said I could not do anything. Well, I can do this journal! And it's worth something!"

"The Journal has shown me that consistency, input and commitment are important. The amount of knowledge I gain from doing the journal is the same as what I put into it"

"Hey! I read a newspaper article that talked about business expenses, and I was able to understand it!"

"I have learnt that thinking about things and writing about them can help you understand them."

The following excerpts illustrate areas of concern revealed by students:

"Sometimes I get confused about the position and performance and what items are expenses and what are purchases of assets"

"Unfortunately this journal is of no use to me as I am too intelligent for this sort of thing"

"I'm not looking forward to my presentation, as I don't think I'll know what to do"

Over Semesters One and Two, 2003 and Semester One, 2004, the final NZ100 examination was marked by the same team of external markers. After the marking process was completed at the end of Semester One, 2004 (the first semester of the implementation of the Reflective Learning Journal) every single marker commented that the standard of the written answers seemed to be higher than in the previous two semesters, and that the written answers were more coherent and easier to follow. These comments lead to the quantitative analysis. With regards quantitative results, please refer to the future research section at the end of this paper.

Discussion and Reflection

Reading the comments (especially at the final hand-in), comparing initial entries and final entries, seeing how students had developed confidence and understanding, and how their communication skills had improved over the course, was, in the main, both illuminating and rewarding.

An unexpected benefit was the access to regular and on-going comment from the students about how they were finding the course. The lecturers were able to see for

441

themselves where students were having difficulty, or where students had achieved insight!

Also unexpected from the TIBF's point-of-view was the realisation that lecturers needed to be prepared to read information and comments that students write about both the lecturers, the course and the paper. The following excerpts illustrate this:

"My teacher is fantastic! Having a great lecturer is playing a big part in me achieving what I set out to achieve at the beginning of the course"

"What I think about this financial statement is not what my lecturer thinks. Actually, sometimes it's hard to know what my lecturer thinks, because they tell all these really stupid stories that don't relate to the course"

"I have enjoyed checking out what my lecturer wears each week"

"I REALLY WISH my lecturer would stop picking on me! If I don't know something, I don't know it!"

Hunter & O'Rourke (1996) sees this as an opportunity to use Reflective Learning Journals as a tool for staff development.

Difficulties encountered with the Reflective Learning Journal assessment were the time required for the implementation, and the establishment and timetabling of the PSD Tutorial groups. The assessment was also time hungry for marking, as turn-around needed to be within 24 – 48 hours.

Reflective Learning Journals as an assessment activity were initially implemented in Semester One, 2004. Because of the responses from both students and staff, and the rewarding results, they were again implemented as an assessment activity in Semester

Two, 2004 and at this time the intention was they would continue to be part of the NZ100 course.

Future Research

As mentioned earlier, (Evaluation of Results) at the end of Semesters One and Two, 2003 and Semester One, 2004, the final NZ100 examination was marked by the same team of external markers. The marks awarded to each student for each question were recorded. There is a future research opportunity to work on quantitative analysis of the marks awarded to the written questions in the final exams of the two semesters prior to the implementation of the Reflective Learning Journal, compared to the marks awarded to the written questions in the final exam of the semester of implementation.

Assessment One
Semester One 2004

REFLECTIVE LEARNING JOURNAL
Worth 7.5 % of Course Mark

ASSIGNMENT COVER SHEET

THIS MUST BE ATTACHED TO THE FRONT OF YOUR REFLECTIVE LEARNING JOURNAL

Family Name

First Name   **Student ID Number**

Programme Name   *NZ Diploma in Business*

Course Name   *NZ100 Accounting Principles*

Lecturer Name

Assessment Number   *ONE*

Due Dates	Week 4	Week 9	Week 13
	Week 6		Week 11

LATE HAND-INS WILL NOT BE ACCEPTED

REFLECTIVE LEARNING JOURNAL

General Description

Throughout the duration of the semester, students are required to maintain a **Reflective Learning Journal.** The purpose of the Journal is to capture your thought processes and ideas.

Each week, students are given a particular topic or question. Students write their **Reflective Learning Journal** their experiences and thoughts on the given topic for the week. The topics are listed on page 5.

Professional Skills Development tutorials will guide you on how to write up your Reflective Learning Journal.

Process

Accounting papers and courses offered by this department are designed to promote the progressive development of communicating and academic competencies. Interpersonal and Communicating Skills are widely recognised by the Accounting profession as critical to successful practice and are recognised by the International Federation of Accountants as a key component of its Professional Skills standards for accountants. We support this by providing a compulsory Professional Skills Development component to core courses. The Reflective Learning Journal is an important tool in which to develop your interpersonal and communicating skills.

All students of NZ100 are allocated a Professional Skills Development tutorial. You are expected to attend this tutorial. Your lecturer will advise you of how to timetable your Professional Skills Development tutorial.

In the Professional Skills Development tutorial you will be assisted to complete your Reflective Learning Journal.

What type of journal do I write in?

You are to keep a hand-written journal. You use a 1B5 exercise book, or similar hard cover book. Make sure your name, id number and the name of your lecturer are clearly written on the front of the book. Use the *Assignment Cover Sheet* for this purpose.

What do I write in my Reflective Learning Journal?

IF YOU CHOOSE, AND IF APPROPRIATE, you may base your journal around three phases of reflection:

1. **What?**
   - What has happened?
   - What activities were involved?
2. **So What?**
   - What do you think about this?
   - What does this mean in relation to your future study? For you personally?
3. **Now What?**
   - What does this mean for next week and the future, for both you and your future study?

If you choose to follow the above 3 phases of reflection, your writings will then probably involve some or all of the following:

- Description of tasks and/or events
- Documenting situations / incidents that connect theory to practice
- Explanation of observations / learning experiences
- Explanation of connections between theoretical principles and personal experience and practice
- Two or three conclusions drawn from personal and practical experience
- Demonstration of critical reflection

How much do I write?

We suggest no more than 300 words for each weekly topic. Quality is more important than quantity.

Where do I hand the Journal in for marking?

All students of NZ100 Accounting Principles are allocated a Professional Skills Development (PSD) tutorial. Journals must be handed in at that tutorial (meaning you MUST attend your Professional Skills Development Tutorials).

All journals will be returned to students either at the next lecture after hand-in, or the first lecture the week following hand-in (which-ever is sooner).

What if I am unable to attend my PSD tutorial?

If you are unable to attend your PSD tutorial, for any reason, you must contact your NZ100 lecturer as soon as possible. This is particularly important if you are unable to attend a PSD tutorial on a hand-in day.

How will it be marked?

If you miss a hand-in, you will automatically lose marks. You will be marked on:

1. Meeting every hand-in;
2. Evidence of maintenance of a weekly learning journal that covers the required topic of the week;

3.   Presentation and Readability:
- Provision of a well-structured and well-laid out document
- Logical, fluent, succinct and mainly correct grammar and spelling.

Weekly Topics

Week 1   Why are you studying accounting?

Week 2   Where did you sit in class in your first week of lectures? How did this affect your understanding of the topic?

Week 3   In your own words, comment on what you see as the purpose of the Statement of Financial Position.

Week 4   In your own words, comment on what you see as the purpose of the Statement of Financial Performance. Also find a newspaper article or clipping that focuses on one of the elements of this statement, and stick this in your journal. You do not need to comment on the clipping.

Week 5   In your own words, comment on the purpose of Balance Day Adjustments. Include in your comments whether or not you think they are necessary and justify your answer.

Week 6   Do you think that a firm that has no Bad Debts, has an appropriate (good or bad) credit policy? Justify your answer.

Week 7   Find a newspaper article or clipping that involves accounting. Stick this in your Reflective Learning Journal, and comment on how it relates to the role of business in society.

Week 8   How do you think what you have learnt in the course so far, could help you earn money in the future?

Week 9   Find a newspaper article or clipping that involves accounting. Stick this in your Reflective Learning Journal, and comment on how it relates to the purpose of accounting.

Week 10   Take a visit to your local supermarket, and see how many internal control procedures you can identify. State, and comment on these internal controls.

Week 11   Why do you think businesses need to have budgets? Do you
           have a budget? Why or why not?

Week 12   Comment on what you think is the most important thing you have
           learnt in the NZ100 course this semester.

Marking Criteria:

Handing In:

For meeting every hand-in   **6 marks**

<u>Variations:</u>
For each hand-in <u>missed</u>   subtract 2 marks per missed hand-in

Maintaining a Journal that meets the required topic:

All topics covered to an acceptable standard   **4 marks**

<u>Variations</u>
All topics covered to a variable standard (AV)   3 marks only
Most topics covered to an acceptable standard (MA) 3 marks only
Most topics covered to a variable standard (MV)   2 marks only
Few topics covered to an acceptable standard (FA) 2 marks only

Provision of a structured and well laid out document   *2 marks*

   <u>Variations</u>

Some structure and reasonably well laid out   1 mark only

Logical, fluent succinct & mainly correct grammar and spelling

                                                                  3 marks
                         <u>Variations</u>
Mostly logical, fluent succinct etc etc   2 marks only
Some logical, fluent and sometimes correct etc etc 1 mark only

TOTAL MARKS   **15 MARKS**

_____

NOTE:

If EVERY hand-in missed, but journal still completed and handed in:

                                             TOTAL OF 2 marks only

2.2 Management Accounting

PRODUCTION COSTS AND COST MANAGEMENT PRACTICES OF TURKISH MANUFACTURING COMPANIES (ICI 500): A DESCRIPTIVE STUDY

Murat Kocsoy, *Bozok University*
Yusuf Ag, *Bozok University*

--Abstract--

In this paper, we aimed to determine the production costs of Turkish manufacturing companies and their managing these costs in order to contribute literature in which no comprehensive study is done on this subject. In accordance with the aim, we conducted a descriptive survey to 287 private manufacturing companies among 500 large-scale companies listed in Istanbul Chamber of Industry and 90 surveys completed by the companies are evaluated.

As a result, the estimation and determination of production costs in the pre-production phase is regarded as a beneficial process. A considerable number of companies continue this process at the beginning and end of production shows their acceptance to traditional cost approach rather than strategic cost management approach of product life cycle. Besides, we found that the relative companies have a low level of association with suppliers which have a significant impact on decreasing and managing costs.

Keywords: Cost Management, Management Accounting, Strategic Cost management, Cost Decreasing, Cost Accounting, Production Cost

1. INTRODUCTION

Since the industrial revolution, technological developments along with changes in economic and social scopes have started to change step by step and especially gained fast from the beginning of 1980s. Those developments eventually cause radical changes in the structure of market. That's why; production cost management that

covers product innovations and designs has become a critical issue in today's business world.

After all developments and changes, in order to survive and make profit in global competitive environment, companies have started to question their traditional production and cost systems with the aim of adaptation to global competition and supplying quick-changing demands and expectations of consumers. Management accountants have realized that traditional costing techniques (like standard costing and cost-volume-profit analysis etc.) become any longer out of date in competitive environment because of changing cost system and increasing in competitive environment of companies. Traditional cost management and cost plus pricing strategies have also lost their influence in this new competitive environment. Because most of the costs are determined in projection and development phase, traditional cost management approaches which consider only the costs in production phase and disregard the other costs in production life cycle have lost their importance. As the companies have increasingly more control over costs in today's competitive market, companies realized that they have much lesser control than they expected as a result of prices mostly determined by increasing competitive market (Gharajedaghi,1999:65). Nowadays, cost is no longer a determinant of market price , just the opposite, market price has become the determinant of cost (Corrigan,1996:24).

In today's intense competitive environment, the production price is unable to be controlled by companies, therefore, the question here for the companies must be; "What should the product cost be according to market price?" rather than " What should the production price be according to production cost?". For this reason, production cost management in the development and projection phase become very critical issue for companies.

452

2. CHANGING COMPANY ENVIRONMENT AND COST MANAGEMENT

What makes cost management very important? The answer is the fact that today's industrial companies face a global competitive environment that is ever-changing and acting by its own rules.

By the technological developments, continuous changes in preference and pleasure of consumers restrict the life cycle of products and services in market-based economies. Marketing approach based on consumers (market) also make fast the restriction/shortening in that life cycle (Tek,2000:24). Besides, the differentiations in the demands of consumers prevent mass production and make it difficult that the industrial companies to benefit from scale economies. make difficult the industrial companies (Can,2004:32). Nowadays, product differentiations and also wide product range for quick supply to consumer demands take the place of mass production for similar type products (Karcıoğlu,1997:4). That eventually causes an increase for fixed cost in its part of unit output (Can,2004:32). At the same time, variety of demands and needs of consumers forces companies to be innovative and improve existing products (Ergun,2002:34).

Under these circumstances, companies can no longer hold a sustainable competitive chance by neither lowering cost nor differentiation strategy in product (Langfield-Smith and Luckett,1999:2). By the leadership in technology as a traditional competitive strategy, quality no longer provides a sustainable competitiveness (Wood,1998:63). Because quality differences between companies is getting decreased. While the quality should be high, costs should be decreased (Ansari et al,1997:4-5). This implies that companies are very effective in managing cost very effectively as well as in managing quality (by total quality management) and functionality (by innovative product projection and development) both (Langfield-Smith and Luckett,1999:2).

Cost management is certainly not a system that determines only product cost. Cost management can be conceptually categorized as; cost decreasing (cost planning) and cost control (Sakurai and Scarbrough,1997:39). Traditional cost systems are based on controlling costs and quality and balancing them temporary, and also focus on internal efficiency. On the contrary, cost management is a process of quality planning and cost decreasing that manages the costs before its occurrence (Ansari et al,1997:6). A well-planned cost management system will provide improvements in quality, cost/price and functionality of a product.

3. PROJECTION-BASED COST MANAGEMENT

Due to rapidly-changing operational environment and intense competition, profit margins of the companies which cannot reduce costs as quickly as their competitors do, will decrease and their survival will be more difficult (Blocher et al,1999:7; Cooper,1995,7).

Hence, cost management has become increasingly crucial for the survival of companies. Cost management requires participation of external and internal contributors from different functions in order to analyze product design, raw material needs and production processes and therefore seek cost-saving opportunities to manufacture products at or below their target cost (Swenson et al,2003,13; Hilton,2005,649). Companies must develop long-term and cooperative relationships by incorporating suppliers being in the first place, distributors, service-providers, company departments, customers and other members of the value chain into cost management process. By this means, cost reduction efforts may spread through the whole value chain (Ansari et al,1997:15-16).

Cost management is considered as a key point that enables to decrease projection costs of product and its processes (Kurunsaari et al,2003:318). Because the production and process technologies are getting more integrated, a product cost becomes more

dependent to its projection (Cooper and Chew,1996:89). At the same time, as product development cycle runs toward the target costing, the projection of product and necessary activities for its production becomes the most significant factor (Langfield-Smith and Luckett,1999:10). Hence, cost management systems aim to make appropriate the projection of product and processes to cost management. While traditional cost-decreasing methods concentrate on scale economies, decreasing waste and improving efficiency in order to manage costs, projection-based cost management places more emphasis on projection phase so as to eliminate probable expensive and time-consuming changes and eventually decreases product cost and its marketing duration (Ansari et al,1997:13).

Nowadays, the life cycle cost of a product, almost more than 80% is fixed and undertaken in the projection and development phases (Freeman,1998:13; Corrigan,1996:53). For instance, 70% production cost of General Motors for truck gears and similarly 80% production cost of Rolls-Royce Company for 2000 product parts occur in projection phase (Doğan,1998:200; Can,2004:34). After projection phase, the flexibility of cost-decreasing becomes largely limited in production phase (Lee,1996:68). Therefore, projection-based cost management is based on the principles of managing cost before its occurrence. Kato states that the projection and development of product is very crucial phase to decrease cost (Kato,1993:35). Even though product costs occur largely in production phase, those costs are mostly determined/ undertaken in projection phase (Ansari et al,1997:13). In other words, while the costs occur in projection and development phase of product life cycle, are future costs; in production phase the accrual costs of related term take place. In production term, because most of the accrual costs occur in production and development phase and are also costs deferred to production phase and here, cost management applies the principles of managing cost along product life cycle

(Hacırüstemoğlu and Şakrak,2002:121; Acar,2005:62; Bahşi and Can,2001:54). Hence, cost management concentrates on projection phase of a product that enables to decrease cost during its all life cycle and examines its influence on all costs from its R&D to its recycling. Cost management encourages all departments of company participated in the process examine their product projection in order to make necessary technical changes before production phase (Ansari et al,1997:13).

Projection analysis includes forecasted production cost as well as undergoing costs after production (like service and assurance costs). The company can figure out whether improvements on products will cause unexpected cost before and after production in customer value and income by examining production cost as well as downstream cost (Blocher et al,2005:7). Thus, most of required changes in product or its projection can be made before production phase. On the other hand, in traditional costing systems most relevant changes are made right after production phase (Ansari et al,1997:13).

4. THE PURPOSE, SCOPE AND CONSTRAINTS OF THE STUDY

4.1. The Purpose of the Study

The purpose of this paper is to determine and to examine the production costs and their management methods of Turkish Manufacturing Companies on which no comprehensive study has been made previously. In accordance with the purpose, a descriptive study is made on private manufacturing companies listed in top 500 index the largest-scale companies yearly reported by Istanbul Chamber of Commerce.

4.2. Universe, Scope and Constraints

The universe of the study consists of the private sector manufacturing companies listed in the "Top 500 Turkish Industrial Entities" announced yearly by the Istanbul Chamber of Commerce (ICI). Within 2007 ICI 500, there are 487 privately-held companies. Of

these, 15 companies which did not want their names to be revealed; and 21 companies operating in mining and electricity production industries which were thought of not suitable for this study, were left out of the scope. Eventually, 451 companies listed in 2007 ICI 500 index made up the universe of the study.

The reason of selecting the companies listed in ICI 500 as the universe of the study is the belief that these companies are more institutionalized and hence they have the strong cost discipline necessary for determining and decreasing of manufacturing costs and that more reliable and consistent information can be derived from these companies.

5. THE METHODOLOGY OF THE STUDY

5.1. Sample Selection, Data Gathering and Survey Preparation

The data used in the study consist of the information gathered via the survey applied to the senior department executives in the ICI 500 companies selected by the simple casual method.

According to the simple casual sample method; when the standard deviation and the variance of the universe are not known, the sample size representing the universe is determined by $n = (\pi(\pi-1) / (e/Z)^2$ formula (Savaş,2003:187). Accordingly, with 95% confidence interval and 5% error margin, the sample size of this study is calculated as $(0,5 \times 0,5) / (0,05 / 1,96^2) = 384$ companies. Because the calculated sample size is larger than 5% of the universe, it is to be derogated by multiplying by the correction factor ((N-n / N-1). According to the formula, correction factor is approximately (451-384 / 451-1) = 0,149. Accordingly the necessary sample size turns out to be 0,149 × 384 = 57 companies. In addition, the questionnaire form was delivered to the 451 companies within the scope primarily via e-mail. Then, appointments were made with 82 of the 109 companies which accepted to response and information was gathered from the executives via face-to-face interviews. Adding the 8 questionnaires which

were seen suitable out of 27 questionnaires sent via fax, e-mail and mail, 90 questionnaires were evaluated. The number of the evaluated questionnaires forms 20% of the universe.

In accordance with the purpose and scope of the study, previous studies and related literature (Kwah,2004:100-103; Borgernas and Fridh,2003:17-30; Dekker and Smidt,2003:299-303; Braxton,1999:33-78; The Consortium for Advanced Manufacturing – International The American Institute of Certified Public Accountants and The University of Akron:1-15) were examined during determination of the survey questions and the scales and preparation of the questionnaire form. Some of the survey questions are multiple-choice and open ended. Others consist of questions rated between "(1)never – (5)always.

5.2. Method of Analysis

No comprehensive research was made in Turkey regarding cost management among manufacturing companies before. Especially there is no information about determination of costs at all.

Descriptive statistical methods such as percentage, frequency and mean were used in the analysis of data obtained from the survey (which was made in order to determine suppliers' cooperation level in the cost determination process). SPSS.16 was used for the analysis of obtained data.

6. EVALUATION OF RESEARCH EVIDENCE

In this section, the number of personnel and the manufacturing methods of the participating companies, and distribution of the respondents of the questionnaire in terms of position, were assessed.

Table 1: Distribution of the Respondent Company Executives According to Positions

	Frequency	Percentage
Engineering	1	1,1%
Accounting/Finance	74	82,2%
Manufacturing/Design	8	8,9%
Marketing	3	3,3%
Other	4	4,4%
Total	**90**	**100%**

In Table 1, distribution of the respondent company executives according to their positions is given. The respondents are senior department executives. Of the respondents, approximately 1% are engineers (cost engineering), 82% percent are accounting-finance managers, 9% are manufacturing and design managers-supervisors, 3% are marketing and purchasing managers and 4% are employees in various departments (management director, auditor, strategic planner and controller). Anket yapılan kişilerin üst yöneticiler olması ve özellikle büyük çoğunluğunun muhasebecilerden oluşması, işletmelerin maliyet yönetimi hakkında daha sağlıklı bilgi alınması açısından önemlidir.

In Table 2, the distribution of the companies in terms of number of personnel is given.

Table 2: Distribution of the Companies In Terms of Number of Personnel

	Frequency	Percentage
100 and below	3	3,3%
101-250	11	12,2%
251-500	22	24,4%
501-1000	21	23,3%
1001-2000	20	22,2%
Above 2000	13	14,4%
Total	**90**	**100%**

According to Tabel 2, approximately 3% of the companies have 100 or less, 12% have 101-250 , 24% have 251-500, 23% have 501-1.000, 22% have 1.001-2.000 and 14% have 2.000 and more employees.

Table 3 shows the company-based distribution in respect of industries and application rate.

Table 3: Distribution of the Companies Based On Industries

	Frequency	Percentage
Automotive	5	5,6%
Electric-Electronic	9	10%
Medical-Optical Instruments	1	1,1%
Medicine	2	2,2%
Machine	3	3,3%
Textile	8	8,9%
Food	14	15,6%
Iron and Steel	10	11,1%
Chemical	7	7,8%
Nonferrous Metals	5	5,6%
Oil-Rubber-Glass	14	15,6%
Paper-Gazette	4	4,4%
Cement	4	4,4%
Others*	4	4,4%
Total	**90**	**100%**

*Forestry and Construction

According to Table 3, the most participatory industries are Food (15,6%), Oil-Rubber-Glass (15,6%), Iron and Steel (11,1%), Electric-Electronic (10%) and Textile (8,9%). The least participatory industries are Medical-Optical Instruments (1,1%), Medicine (2,2%), Machine (3,3%), Paper-Gazette (4,4%), Cement (4,4%), Forestry and Construction (4,4%), Nonferrous Metals (5,6%), Automotive (5,6%) and Chemical (7,9%) Industries.

Table 4 shows distribution of the manufacturing methods of the companies.

Table 4: Distribution of the Manufacturing Methods of the Companies

	Frequency	Percentage
Large-Scaled, Assembly-Oriented Manufacturing	27	30%
Small-Scaled, Assembly-Oriented Manufacturing	2	2,2%

Large-Scaled, Process-Dependent Manufacturing	30	33,3%
Small-Scaled, Process-Dependent Manufacturing	3	3,3%
Custom Order Manufacturing-Assembly	28	31,1%
Total	**90**	**100%**

According to Table 4, approximately 37% of the participated companies have process-dependent manufacturing methods and 63% have assembly-oriented manufacturing methods.

According to these findings, it emphasizes the importance of our paper that most of the respondent companies have common assembly-oriented processes. Because those companies out-source much more components compared with process-oriented manufacturing companies, that's why; they should place more emphasis on cost management.

The competition environment of the participating companies using target costing or similar methods was aimed to determine by directing questions to the executives about how they perceive their operation environments. The results are presented in Table 5.

Table 5: Factors Related to the Operation Environments of the Companies

	N	Very Low	Low	Normal	High	Very High	Mean	Mode
Potential of estimating the operations of the competitors	90	2 2,2%	18 20%	49 54,4%	13 14,4%	8 8,9%	3,08	3
Degree of change in customer joy and expectations in the last 5 years	90	4 4,4%	10 11,1 %	25 27,8%	37 41,1%	14 15,6%	3,52	4
Degree of change in economic, legal and political circumstances in the last 5 years	90	1 1,1%	3 3,3%	33 36,7 %	45 50%	8 8,9%	3,62	4
Degree of change in manufacturing processes and technologies	90	-	4 4,4%	28 31,1%	43 47,8%	15 16,7%	3,77	4
Intensity of the competition	90	-	2	16	40	32	4,1	4

			2,2%	17,8%	44,4%	35,6%	3	
the company faces in the market								

According to the data presented in Table 5; it is realized that most of the companies operate in an environment of very high ambiguity and competition.. Therefore, the use of cost management in the markets with environmental ambiguity and high competition is quite important for the success of the companies. In conclusion, it can be claimed that there is an increasing competition combined with a dynamic environment, and this situation emphasize the importance of cost management for the success of company in cost-decreasing.

The enterprises included in the research were asked several questions concerning the stages they make cost estimation which is made at several stages for determining cost of new products and the attained results are presented in Table 6.

Table 6: Timing of New Products Cost Estimation in the Enterprises

	No idea	Yes	No	Total
After the mental determination of the new product	9 (10%)	55 (61,1%)	26 (28,9%)	90 (100%)
During the design stage of the new product	6 (6,7%)	71 (78,9%)	13 (14,4%)	90 (100%)
After beginning the production of the new product	2 (2,2%)	49 (54,4%)	39 (43,3%)	90 (100%)
After the completion of production	3 (3,3%)	25 (27,8%)	62 (68,9%)	90 (100%)
Cost estimation is not done in any stage	-	4 (4,4%)	86 (95,6%)	90 (100%)

According to Table 6, respondent enterprises make cost estimations seriously and systematically, by 61,1% percent "after the identification of product as a concept", by 78,9% "during the product designation phase" and by 54,4% "After beginning the production of the product". Hereby, it is desirable result for mentality of projection-oriented cost management that cost estimations of relevant companies center in pre-production phase, especially in product projection phase. Because in projection-oriented cost management, by market research, necessary target cost is determined in accordance with the expected functionality and quality and at the same time desired

profit margins, and then the product is projected according to this target cost or cost estimation, instead of waiting for actual cost after production is started. In other words, the costs that will exist during life cycle of the product are determined at pre-production designation phase and the production is done in line with these costs after the designation. So all the costs concerning product are estimated or determined at pre-production phase. Also, the fact that 43,3% of the enterprises states they do not make any cost estimation "after the beginning of the production" and 68,9% of these enterprises do not make any cost estimation "after the end of production" and 4,4% of these do not make any cost estimation. These results show that most enterprises apply partially the projection-oriented cost management.

As a result of these findings, it is considered as positive for the mentality of projection-oriented cost management that most companies estimate their product costs in pre-production phases. Besides, nearly 45,6% of those companies do this "after the beginning of production", 27,8 of those do "at the end of production" show that those companies determine their product costs according to traditional costing approaches. That result contradicts with the mentality of projection-oriented cost management. While traditional approaches focus on determination and controlling of post-production costs, the projection-oriented cost management is based on the management and determination of costs before the materialization of costs. Therefore, the projection-oriented cost management necessitates a cost estimation system that provide an increasing accuracy level from the concept phase of a product until being ready for the designation and an extensive cost planning.

In order to identify the extent of the cost estimation systems and cost planning, the cost components that take place in the cost estimation of a new product were asked to the enterprises included in the research and the results are presented in the Table 7.

Table 7: Cost Components in the Cost Estimation of Enterprises

	Involving	Not Involving	Total
Pre-manufacturing Costs (R&D, Market Research etc.)	58 (64,4%)	32 (35,6%)	90 (100%)
Manufacturing Costs	88 (97,8%)	2 (2,2%)	90 (100%)
Marketing Costs (advertisement, promotion, sale etc.)	77 (85,6%)	13 (14,4%)	90 (100%)
Distribution/Logistic Costs	74 (82,2%)	16 (17,8%)	90 (100%)
Service/Support Costs (Repair-Maintenance, Guarantee etc.)	51 (56,7%)	39 (43,3%)	90 (100%)
Recycling Costs	44 (48,9%)	46 (51,1%)	90 (100%)

According to Table 7, 64,4% of the enterprises uses "pre-production costs", 97,8% uses "production costs", 85,6% uses "marketing costs", 82,2% uses "distribution/logistics costs", 56,7 % uses "service/support costs" and 48,9% uses "recycling costs" in the cost estimations.

Accordingly, by almost all companies, the estimation and determination production costs as the cost component in the pre-production phase is an expected situation for the mentality of the projection-oriented cost management. On the other hand the number of enterprises that estimate pre-production costs like market research and research/development (R&D) costs is lower than the expected for the projection-oriented cost management. As reasons for this result, giving inadequate importance to market research especially to customer analysis and also allocating insufficient resources for R&D activities can be considered. So it can be said that no estimation and cost planning regarding these cost components are made. Similarly, it can not be said that the number of enterprises that estimate service and recycling costs in the pre-production phase is high. However, the majority of enterprises' inclusion of marketing and distribution costs in the cost calculation as the cost component of a new products is a positive situation for the success of the projection-oriented cost management.

The companies unfamiliar with projection-based cost management apply mostly traditional costing approaches and tend to focus on only production phase and disregard the costs of other product life cycle. For this reason, it is concluded that those companies are not familiar with the approach of costing during product life cycle for the success of projection-oriented cost management.

The replies of the enterprises which involve in the research and makes cost estimation activities for the questions regarding cost determination and determination participation rate of departments and value chain members to cost decreasing process are presented in Table 8.

Table 8: Participation Rate of Departments and Value Chain Members to Cost Estimation and Cost Decreasing Process of Enterprises

	N	Never	Rarely	Sometimes	Usually	Always	Mean	Mode
Accounting/Finance	90	6 6,7%	8 8,9%	22 24,4%	18 20,0%	36 40,0%	3,78	5
Sales/Marketing	90	6 6,7%	3 3,3%	20 22,2%	27 30,0%	34 37,8%	3,89	5
Product Planning and Design Engineering	90	8 8,9%	4 4,4%	33 36,7%	13 14,4%	32 35,6%	3,63	3
Purchasing	90	9 10,0%	4 4,4%	33 36,7%	20 22,2%	24 26,7%	3,51	3
Production	90	3 3,3%	5 5,6%	23 25,6%	22 24,4%	37 41,1%	3,94	5
Quality Assurance	90	11 12,2%	12 13,3%	29 32,2%	17 18,9%	21 23,3	3,28	3
Distribution/Logistic	90	24 26,7%	16 17,8%	32 35,6%	8 8,9%	10 11,1%	2,60	3
Suppliers	90	34 37,8%	7 7,8%	35 38,9%	8 8,9%	6 6,7%	2,39	3

According to these results, participation level of departments in interdepartmental composed costing teams cannot be said to be high. Lower participation rate (2,39 –

15,6%[56]) of suppliers which should be the most important members of costing teams, is a constraint for the success of cost decreasing and management.

It is found that because the companies unfamiliar with projection-oriented cost management apply traditional cost management, generally interdepartmental participants in cost estimation and decreasing process are mostly organized from sale/marketing, accounting/finance and especially participation of people in production department. Besides, it can be said that the reason of the fact that the member of the value chain participated in cost estimation and decreasing processes is not at enough number is that those companies are unfamiliar about the approach of costing during product life cycle.

As a result of this data, it is impossible to be successful if the interdepartmentally composed teams are not utilized in product cost estimation and cost decreasing process or the necessary important is not given. At the same time, it can be said that the utilization level and structure of interdepartmentally composed teams depends on enterprises' adoption level of product life cycle costing approach and the scope cost planning.

The results regarding the application level of the activities that the enterprises involved in the research do for decreasing the product costs are presented in Table 9.

Table 9: Application Level of Strategies That Will Be Followed By Companies When Costs Foreseen In the Projection Phase Is Exceeded

	N	Never	Rarely	Sometimes	Usually	Always	Mean	Mode
The estimated sale price of the product is increased	90	12 13,3%	13 14,4%	31 34,4%	31 34,4%	3 3,3%	3,00	3
The expected profit margin from the product is	90	6 6,7%	11 12,2%	42 46,7%	28 31,1%	3 3,3%	3,12	3

---

[56] Percentages amount the sum of Usually and Always options.

decreased								
The features and functionality of the product are decreased	90	67 74,4%	11 12,2%	11 12,2%	-	1 1,1%	1,41	1
The cost targets of the product are increased	90	53 58,9%	15 16,7%	15 16,7%	6 6,7%	1 1,1%	1,74	1
The product is abandoned	25	27 30%	20 22,2%	34 37,8%	6 6,7%	3 3,3%	2,31	3

According to these data, most of the companies give priority to decreasing the amount of profit expected(3,12 – 34,4% [57]) and increasing the foreseen price of the product(3,00 – 37,7%) strategies. Decreasing the profit margin by the management which is determined according to the strategic purposes of the firm may be an appropriate strategy to increase the market share of the product and to position it in the market. Although decreasing the target profit margin may seem negative at first glance, with an increase in sales related with market conditions or with an decrease in the cost of the product related with its lifecycle, reaching the targeted profit rate will be possible. Secondly, in the projection-oriented cost management, increasing of target sale price, which should be determined according to wishes and solvency of customers, maybe is the last strategy to apply. Because in the competitive market conditions, acting with cost-plus pricing contrasts strongly with projection-oriented cost management. In order to determine a high price level, product should be really new product which can raise its value perceived by customers and should be different from its rival products or business should have the monopolist or price determining position in the market. But, this situation should be carefully analyzed in terms of market share or sales volume which will enable the level of profitability which the business desires. The third strategy of companies to define the implementation degree is either abandoning the product or disapproving [discarding] its production (2,31 - 10%) as a last resort. Because, too much time and effort has been allocated to the product. Although in successfully implemented projection-oriented cost management, the possibility of abandoning the

---

[57] Percentages amount the sum of Usually and Always options.

product is too low, this strategy should be resorted just in the cases where alternative solutions exhausted for achieving cost targeting. However manufacturing of any product that doesn't contribute to the strategic goals of the business should not be let. The fourth strategy of companies for implementation degree is shrinking product qualities and functions (1,41 – 1,1%). This strategy should be implemented if diminishing qualities of the product affect market price, which is used for determining the cost targets, positively. The strategy of raising cost targets of a product (1,74 – 7,8%) should be resorted in extra-ordinary cases if presence of a specific product increases the demand of other products that enforces continuation of the product line; or in cases on time product supply prevents market share and income loss. In such cases cost increases should be dealt immediately by over viewing design process in detail and developing other counter measures. Incautious measures distort necessary discipline for achieving cost targets.

Consequently, companies' primary strategy of increasing selling prices affects the implication of cost targeting negatively. Scarce need for application of increasing cost targets strategy is particularly good.

The results regarding the application level of the activities that the enterprises involved in the research do for decreasing the product costs are presented in Table 10.

Table 10: Application Level of the Cost Decreasing Activities Done by the Enterprises

	N	Never	Rarely	Sometimes	Usually	Always	Mean	Mode
Trying to supply inexpensive materials and parts without making concessions on quality	90	4 4,4%	3 3,3%	7 7,8%	32 35,6%	44 48,9%	4,21	5
Using low quality and more inexpensive materials and parts	90	69 76,7%	13 14,4%	5 5,6%	1 1,1%	2 2,2%	1,38	1
Focusing on product	90	8	13	17	34	18	3,46	4

design		8,9%	14,4%	18,9%	37,8%	20%		
Removing the features and functions that increase the cost of the product	90	36 40%	19 21,1%	27 30%	5 5,6%	3 3,3%	2,11	1
Redesigning the pre and post-production processes by continuously reviewing them	90	5 5,6%	10 11,1%	14 15,6%	28 31,1%	33 36,7%	3,82	5

In Table 10, the cost decreasing activities of the enterprises according to application level are respectively; "trying to supply cheaper materials and parts without compromising quality" (4,21 – 84,5%[58]), "examining and redesigning pre and post-production phases" (3,82 – 67,8,3%), "concentrating on product design" (3,46 – 57,8%), "extracting the features and functions that increases the product cost" (2,11 – 8,9%) and "using low-quality materials and parts" (1,38 – 3,3%).

According to these results, it can be said that a majority of the firms tend to behave according to the approach of projection-oriented cost management in order to decrease the costs of the products. Because projection-oriented cost management is a strategic profit and cost management process which aims at decreasing the total costs throughout the lifecycle of the product by concentrating on its design which will enable it to be produced at a cost level that will enable the firm to reach the target profit level or market share without giving concessions from the quality, specialty and functioning of the product that the customers are expecting and are willing top pay for. As understood from this definition, in the projection-oriented cost management, neither low quality inputs should be used or the functions and features that the customer is willing to pay for should not be extracted from the product in order to decrease costs. On the contrary, the projection-oriented cost management underlines the fact that a firm should reach and go beyond the rival products in every one of these components in order to sustain its competitiveness. At the same time, projection-oriented cost management accepts the design of products and processes as the critical point of cost

---

[58] Percentages amount the sum of Usually and Always options.

management and cost decreasing. Because more than 80% of the lifecycle cost of a product is determined during the design and development stage and because the product and process technologies begin to be more integrated, both the design of the product and the activities needed to produce the product is the most important factor for cost decreasing. This is why during the projection-oriented cost management process, by focusing on the design, which will enable cost decreasing throughout the lifecycle, it is determined whether the design may or may not cause after production costs which are not appropriate for customer value and income. Thus, in this way some time consuming and expensive changes that might be faced are eliminated beforehand and both the cost of the product and market entrance period is decreased.

7. CONCLUSION

Since the industrial revolution, technological developments along with changes in economic and social scopes have started to change step by step and especially gained fast from the beginning of 1980s. Those developments eventually cause radical changes in the structure of market where companies operate. That's why; production cost management that covers product innovations and designs has become a critical issue in today's business world.

The primary results of this evaluation study of the application level of the projection-oriented cost management among the Turkish manufacturing enterprises (ICI 500) can be summarized as follows:

- Majority of the companies operate in competitive market conditions increasing important of the projection-oriented cost management.

- Majority of the companies apply partially projection-oriented cost management.

- While most of the sample companies include costs of pre-production, production and marketing in estimations of product cost, almost half of the sample companies disregard service/maintenance cost along with recycling cost in cost estimations, restrict the success of cost management. This shows that the application of product-life-cycle costing is not implemented properly by companies.

- Business segments' and especially suppliers' low-level participation in cost-reduction efforts will be an important constraint in reducing costs at will. Finally, the role of suppliers is very limited in cost management in Turkish companies

- Majority of the companies tend to behave according to projection-oriented cost management in order to decrease the costs of the products.

THE EFFECTS OF MANAGEMENT DEMOGRAPHY ON AUDITOR CHOICE AND EARNINGS MANAGEMENT: EVIDENCE FROM CHINA

Louis T. W. Cheng, Hong Kong Polytechnic University, Hong Kong
T. Y. Leung, City University of Hong Kong, Hong Kong

Abstract

The literature shows that audit quality and earnings management are related. In addition, there is also some evidence revealing that higher quality auditors provide significant external governance. As top management plays a vital role in designing and implementing corporate governance policy, we conjecture that management demography and internal corporate governance characteristics affect auditor choice, which in turn together with management demography influence earnings management. Using a sample of 3,881 firm-year observations between 2001 and 2005 in China, we find that a board employing a chairperson with professional or academic certification (i.e., holding titles) and a higher percentage of independent directors tends to hire better quality auditors. Furthermore, chairpersons with titles and longer tenure conduct less earnings management. Our results are robust using different measures of auditor quality and discretionary accruals.

Keywords: Auditor quality; Management demography; Corporate governance; Earnings management

1. Introduction

Controlling for corporate governance and firm characteristics, this study examines how management demography affects auditor choice and hence earnings management. Our hypothesis is based on three areas of literature: 1) the effects of audit quality on earnings management; 2) the relation between corporate governance and audit quality; and 3) the influence of management demography on corporate behavior. While little research has been done in the literature in examining the relations between management demography and accounting decisions, management theories long ago have recognized the important role of top management in determining the success of a firm. In particular, the upper echelons theory by Hambrick and Mason (1984) and Hambrick (2007) suggest that demographic characteristics of top executives can play a significant role in shaping organizational outcomes. Also, the resource-based view of firms by Barney (1991) and Hitt, Bierman, Shimizu, and Kochhar (2001) propose that human capital is a crucial intangible asset for firm operation and decision.

The accounting literature clearly demonstrates some relations among corporate governance, audit quality and earnings management. Extending the

assertions of upper echelons theory and resource-based view, we conjecture that top management demography plays a vital role in influencing the design and implementation of corporate governance policy. As Fan and Wong (2005) conclude that auditors serve as an external corporate governance tool, especially in emerging markets, we hypothesize that management demography affects auditor choice. Finally, we further conjecture that management demography and audit quality jointly influence earnings management.

Employing 3,881 firm-year observations between 2001 and 2005 in China, we find evidence to support our hypothesis that chairpersons with professional or academic titles and a board with a higher percentage of independent directors hire better quality auditors. Furthermore, chairpersons with titles and longer tenure conduct less earnings management. Our results are robust using different measures of auditor quality and earnings management. Following this introduction is the section on theoretical background and hypothesis. The data and methodology are described in Section 3. We present the empirical results in Section 4 and conclude our study in Section 5.

2. Theoretical Background and Hypothesis

Corporate governance and audit quality

Past corporate governance literature mainly focuses on board governance and its effects on performance (Lee, Rosenstein, Rangan and Davidson 1992; Yermack 1996). In particular, Xie, Davidson and DaDalt (2003) suggest that an active board should perform the monitoring function better than an inactive board. Francis, Khurana, and Pereira (2003) report that the demand for high quality auditor is lower for countries with weaker legal environment than for the countries with stronger legal environment.

Fan and Wong (2005) argue that as the agency conflicts between controlling shareholders and minority shareholders are difficult to be resolved by traditional

corporate control tools such as board of directors, auditors can serve as an external agent to take up an important corporate governance role, particularly in emerging markets. Choi and Wong (2007) further find that auditors play a more important role in corporate governance in countries with weak rather than strong legal institutions.

Audit quality and earnings management

Previous studies in audit literature cover extensively on the relation between agency problems (Francis and Wilson 1988; DeFond 1992) or institutional including legal, political and economic factors and choice of auditors (Choi and Wong 2007; Wang, Wong and Xia 2008). Here we focus on the relations between audit quality and earnings management. Auditors can help to solve an agency problem of adverse selection by enhancing the credibility and informativeness of financial reports (Becker, DeFond, Jiambalvo and Subramanyan 1998). Based on this argument, better audit quality should lead to stronger public and market pressure for a firm to engage in earnings management. In fact, the literature has recently documented some international evidence for the effects of audit quality on earnings management. Tendeloo and Vanstraelen (2008) find that high quality auditors provide a constraint on earnings management for private firms in European countries. Chen, Chen, Lobo, and Wang (2008) show that state-owned and family-owned firms in China using high quality auditors conduct less earnings management. In short, these studies provide the necessary foundation for us to propose the possible moderation effect for management demography on the audit quality-earnings management relation.

Management demography and corporate behavior

Early literature in management (Hall 1977) and population ecology (Hannan and Freeman 1977) suggest that organizational outcomes including performance are mainly determined by bureaucratic rules and environmental selection. Then a recently emerging management theory, upper echelons theory (Hambrick and Mason 1984; Hambrick 2007), proposes a new perspective and argues that top management makes

a difference and is key factor in shaping organizational outcomes. Under the upper echelons literature, common management demographic characteristics that have a significant influence on organizational outcomes include gender (Farrell and Hersch 2005), education level (Boyatzis 2004), age, and tenure (Barker and Mueller 2002). Another popular management theory, resource-based view (RBV), echoes back a similar argument. From the RBV perspective, human capital is an essential intangible asset for firm operations (Hitt, Bierman, Shimizu, and Kochhar 2001). Both theories suggest that top executives represent an essential resource for the firm to generate superior performance.

Why China and why chairperson of the board?

There are several reasons why we choose the Chinese market for our study. China is one of the largest and fastest-growing emerging markets in the world. The growing economic significance of the Chinese market in the global economy arouses the attention of the local and international investors to the issue about the right type of top executives for effective management and corporate governance practice. Despite the rapid economic growth, the development of the financial infrastructure and regulatory system are still not mature. The Chinese market is characterized with concentrated ownership by controlling shareholders and weak legal institutional environment. In such kind of legal environment, investor protection is inadequate (La Porta, Lopez-De-Silanes and Shleifer 1999). Poorer corporate governance system may lead to lower demand of audit quality (DeFond, Wong and Li 2000).

DeFond, Wong and Li (2000) propose several institutional characteristics that impede the supply and demand of high quality audits in the Chinese market.[59] Gul,

---

[59] Some of the impediments are a lack of corporate governance mechanisms for investor protection; government ownership of state-owned enterprises (SOEs) and audit firms and the perverse management incentives due to government ownership.

Sun and Tsui (2003) find the market reaction to earnings increase is stronger for firms with high quality auditors. Chan, Lin and Mo (2006) show that after receiving qualified opinions, the local government-owned-firms switch from non-local to local auditors to achieve opinion shopping. Wang, Wong and Xia (2008) provide evidence that three institutional factors of extent of state ownership, level of market and legal development and degree of government power over auditors affect auditor choice.

In short, in an emerging market like China where the government is the controlling shareholders of many listed SOEs in the market and a large proportion of domestic CPA firms are related to the government directly or indirectly, there is a question how the auditors may work with top management in China to perform their monitoring function. Therefore, it is important to explore the relation between management demography and choice of auditors in China.

The next issue needed discussion is why we study chairperson instead of chief executive officer (CEO) or general managers. The management structure is different between the US (or Europe) and China. The chairperson ranks higher than the CEO in the firm and is usually the highest paid executive (Firth, Fung and Rui 2006). Li and Yang (2003) even point out that the chairpersons in China involve in the daily management and operation of the firms.

Hypothesis

Our hypotheses can be divided into two separate but consecutive parts. The first part deals with how management demography affects auditor choice. The second part examines how management demography and auditor choice together may affect earnings management. Based on the three areas of literature discussed above, we can draw the following concluding argument. Top managers shape corporate culture with its management philosophy, which directly influence how the corporate governance policies are implemented. The choice of auditor is an issue relating to corporate governance of the firm. In addition, auditors play an important part in

479

influencing management reporting discretion. Extending the argument of Fan and Wong (2005) which suggests that auditors can serve as an external agent to perform the corporate governance function, we conjecture that the internal governance characteristics are related to management demography, which affects the external governance monitoring mechanism: the choice of auditor. This is the first part of our hypothesis.

Second, the selection of auditor and earnings management strategy are major decisions to be made by top executives. The literature has already shown that there is a relation between audit quality and earnings management. Extending the first part of our hypothesis here, we hypothesize that management demography and audit quality jointly influence the financial reporting discretion and consequently the level of earnings management of the firm. We formulate the following general hypothesis:

H1:   *The demographic characteristics of a chairperson are related to auditor quality and magnitude of earnings management.*

Based on the five demographic characteristics of the chairperson (title ownership, gender, tenure, age and education level) in the subsequent empirical analysis, we formulate five sub-hypotheses to delineate their respective influence on audit quality and earning management.

<u>Title ownership</u>

In addition to the common demographic characteristics (gender, education level, age, and tenure) suggested by the upper echelons literature, we propose to add a new demographic characteristic namely "title" (i.e., professional and academic certification status) of chairperson in our study. Certification status can be defined as receiving professional and academic certification such as certified public accountants (CPAs), certified engineers, and professorship. Sollenberger (1986) shows that Chinese have a long tradition in pursuing personal certification through higher education and professional qualifications. We expect that there is an association of employment of

quality auditor and title ownership of chairperson. The chairpersons with title status would tend to use higher quality auditors as titled chairpersons believe in the importance of higher audit quality. In addition, based on our argument of titled chairpersons employing higher quality auditor and the literature that the employment of higher quality auditor would lead to less earnings management, we can expect that titled chairpersons would be associated with less earnings management.

H1a: Chairperson's title is positively related to audit quality and negatively related to magnitude of earnings management.

Gender

An increasing number of females have taken up the senior executive positions in the traditionally male-dominating business world. There are a number of studies examining the aggressiveness, leadership ability and qualifications of executives (Schein 1973; 1975) and find that both male and female managers perceive that males are more likely to possess the characteristics associated with managerial success. Kalleberg and Leicht (1991) find that it is more likely for male executives than the female counterparts to accept and undertake innovative corporate strategies and business projects. Therefore, we expect that there should be a difference for firms chaired by female or male on the decisions of auditor choice and earnings management in a culturally masculine society like China.

H1b: There is a difference in the decisions for auditor choice and earnings management for firms led by female and male chairpersons.

Tenure and age

Management literature indicates that tenure of managers is related to the propensity to accept new changes and risk. Hambrick and Fukutomi (1991) find that as tenure increases, CEOs tend to make fewer changes in corporate strategy. In addition, Hambrick and Mason (1984) suggest that older top managers, as compared to younger top managers, are more conservative and risk averse. We expect more experienced

and older chairperson should be more conservative than less experienced and younger chairperson. Therefore, more experienced and older chairperson should choose higher quality auditor and be less likely to engage in earnings management activity.

H1c: *Chairperson's tenure is positively related to audit quality and negatively related to magnitude of earnings management.*

H1d: *Chairperson's age is positively related to audit quality and negatively related to magnitude of earnings management.*

Education level

In the upper echelons literature, education level is related to open mindedness and ability to evaluate alternatives (Herrmann and Datta 2002). Wally and Baum (1994) find that more educated top executives are less conservative. Therefore, we expect that more educated chairperson should be less conservative in auditor choice and more aggressive in financial reporting decision to engage in earnings management activity.

H1e: *Chairperson's education level is negatively related to audit quality and positively related to magnitude of earnings management.*

3. Data and Methodology

We retrieve our data of all firms (except those in the finance industry) listed on the Shanghai Stock Exchange and Shenzhen Stock Exchange in our sample period over five years between 2001 and 2005 from the China Securities Markets and Accounting Research Database (CSMAR) and Wind Financial database (WindDB). After matching all the management demographic and firm level data, there are 3,881 firm-year observations in our sample.

3.1 Regression Model

We examine the relation between earnings management, auditor choice and management demography through the following two-stage least-square regression models (1) and (2):

$$AQD = \alpha_0 + \beta_1 \text{ Title} + \beta_2 \text{ Gender} + \beta_3 \text{ Tenure} + \beta_4 \text{ Age} + \beta_5 \text{ Edu} + \beta_6 \text{ BoardSize}$$
$$+ \beta_7 \text{ IndDirRatio} + \beta_8 \text{ DirHolding} + \beta_9 \text{ EPS} + \beta_{10} \text{ DA} + \beta_{11} \text{ MB} + \beta_{12} \text{ LnAsset}$$
$$+ \beta_{13} \text{ ForeignD} + \beta_{14} \text{ NonSOED} + \beta_{15} \text{ Develop} + \beta_t \sum_t \text{Year}_t + \beta_j \sum_j \text{ Industry}_j$$

$$(1)$$

$$EM = \alpha_0 + \beta_1 \text{ FVAQD} + \beta_2 \text{ Title} + \beta_3 \text{ Gender} + \beta_4 \text{ Tenure} + \beta_5 \text{ Age} + \beta_6 \text{ Edu} + \beta_7 \text{ BoardSize}$$
$$+ \beta_8 \text{ IndDirRatio} + \beta_9 \text{ DirHolding} + \beta_{10} \text{ EPS} + \beta_{11} \text{ DA} + \beta_{12} \text{ MB} + \beta_{13} \text{ LnAsset}$$
$$+ \beta_{14} \text{ NonSOED} + \beta_t \sum_t \text{Year}_t + \beta_j \sum_j \text{ Industry}_j$$

$$(2)$$

3.2 Measurement of Auditor Quality

In the audit literature, market share in terms of revenue or audited assets of an audit firm is used to measure audit quality (e.g., Becker, DeFond, Jiambalvo and Subramanyam 1998). Thus international Big-N CPA firms (previously Big 8, then Big 6, and then Big 5, and now Big 4) are used as a proxy for higher quality (DeAngelo 1981; Gul and Tsui 1998). Studies using Chinese firms also use total audited assets of clients to rank auditors to proxy audit quality (DeFond, Wong and Li 2000). DeFond et al show that firms audited by Top 10 auditors have better audit quality than firms audited by non-Top 10 auditors.

However, in developing markets such as China, the audit market is still mainly dominated by the government-affiliated or domestic CPA firms in terms of the number of clients. For instance, in terms of revenue, the international Big-4 firms do rank the highest four audit firms between 2002 and 2005 in China[60]. However, in terms of

---

[60] Based on the information of www.esnai.com, the total revenues earned by the Big-4 CPA

audited assets, one of the Big-4 international CPA firm cannot make it to the top 10 during the same period. Recently, Wang, Wong and Xia (2008) provide three reasons why local and smaller auditors in China are actually preferred by local and central SOEs[61].

Based on the methodology of DeFond, Wong and Li (2000), we use the market share (in terms of audited assets) of an audit firm as a proxy of auditor quality. First we construct an annual list of auditor by market share. Basically, we compute the total audited assets for each auditor per year. Based on this list, we can rank the auditors by market share, which proxies their quality. Our proxy of auditor quality is the traditional measure of a dummy variable (AQD). We construct three versions of AQD (AQD1 for Top 5, AQD2 for Top 10, and AQD3 for Top 15). For instance, AQD1 is coded 1 if the audit firm is in the Top-5 category and 0 otherwise.

3.3 Measurement of Earnings Management (EM)

Large audit firms have more reputation capital at stake and hence should be more resistant to management pressure not to report contract breach (DeAngelo 1981).

---

firms between 2002 and 2005 are RMB4,718,368,200 for PriceWaterhouse and Coopers, RMB2,462,856,400 for Ernst and Young (HuaMing and DaHua), RMB2,234,605,300 for Deloitte and RMB2,396,702,400 for KPMG.

[61] Wang, Wong and Xia (2008) mention several reasons why the local and central SOEs prefer small local auditors rather than Top 10 or non-local auditors. One reason is the preferential treatments given to the local and central SOEs in the product and capital markets by the stock market regulators and the government's or state's banks (Brandt and Li 2003). In addition, as the outside shareholders expect the government to provide bailout to the SOEs in times of financial problems, the SOEs have a weaker demand for Top 10 auditors to provide financial insurance or to mitigate the agency problems. Another reason for the preference to the small local audit firms by the SOEs is that the small local auditors have specialized knowledge of the local government and of the SOEs which are in the same regions.

Therefore, higher audit quality can help constraining the magnitude of earnings management. Becker, DeFond, Jiambalvo and Subramanyam (1998) find that there is a larger discretionary accrual reported by non-Big 6 auditors (lower audit quality) than by Big 6 auditors (higher audit quality). As a result, we expect a negative relation between auditor quality and earnings management. We have two measures of EM. The first measure is the modified Jones model (Dechow, Sloan and Sweeney 1995) (MJAC). The second measure is the performance-matched discretionary accrual model (PMAC) of Kothari, Leone and Wasley (2005).[62] We use the absolute values of MJAC and PMAC to examine the magnitude of earnings management.

3.4 Measurement of Management Demography

Based on our hypothesis, the five personal attributes of chairpersons we examine are title, gender, tenure (year of experience as chairperson), age, and education level. Title is a dummy variable for title, which is coded 1 if the chairperson holds a title (academic title or professional title) and 0 otherwise. We use Gender, which is a dummy variable coded 1 if the chairperson is a female and 0 otherwise to test if there is a difference in auditor choice and earnings management. Tenure is a measure of experience, which is the number of years the chairperson stays in office. Age is the age of chairperson. Edu is a dummy variable coded 1 if the chairperson has a four-year university degree or above and 0 otherwise.

3.5 Control Variables

Measurement of Board Governance Factors

---

[62] We also use the performance-matched discretionary accrual model because this method controls for the effect of performance on discretionary accrual which improves the reliability of inferences from earnings management. We use the current year's return on assets (ROA_t) as the additional performance matching variable in the modified Jones model (Dechow, Sloan and Sweeney 1995) to estimate the performance matched discretionary accrual each year for each industry.

Fama (1980) argues that the directors on the board should be effective monitors and are important governance mechanisms as they have their reputation at stake in the director labor market. One of the functions of the board of directors is to oversee firm management. A good-governed board represents a good internal corporate governance mechanism and hence would be expected to have a high quality external monitoring agent (auditor) to oversee the firm's financial reporting process. We include board size (BoardSize), independent director ratio (IndDirRatio), and percentage of directors' shareholding (DirHolding) as the corporate governance factors in our model.

DirHolding is the ownership percentage of all directors on board. Agency theory suggests that awarding firm shares to top managers can help reduce conflict of interests between managers and shareholders (Jensen and Meckling 1976). Therefore, the percentage of directors' shareholding is related to standard of corporate governance, and hence the choice of auditor. In addition, Warfield, Wild and Wild (1995) argue that the percentage of managerial ownership is an important factor of discretionary accruals and find a negative relation between managerial ownership and accruals.

Firm Financial Measures

We include several financial measures (EPS, DA, MB and LnAsset) of firms in our model as control variables. EPS is earnings per share. DA is debt to asset ratio which is a measure of firm risk. Information asymmetry is positively related to firm risk. MB is ratio of market value to book value of equity. LnAsset is log of total assets which is a measure of firm size.

Firm Demographic Characteristics

We have three firm demographic characteristics (ForeignD, NonSOED and Develop) in our model. The financial statements of firms with foreign investors (B-shares r H-shares) have to be prepared according to International Accounting

Standards and to be audited by international CPA firms. We have to include the variable, ForeignD, in the model as the fact whether the firms issue foreign shares would affect the choice of auditor. ForeignD is a dummy variable coded 1 if the firm issues domestic A-shares and B-shares or H-shares and 0 otherwise.

Wang, Wong and Xia (2008) find that the institutional factors (both economic and political) of the extent of state ownership and level of market development affect auditor choice in the Chinese market. Therefore, we include NonSOED and Develop in the model as control variables. NonSOED is a dummy variable coded 1 if the firm is a non-state-owned enterprise and 0 otherwise. It is expected that the demand for auditor quality to play a monitoring role and likelihood to engage in earnings management activity are higher for non-SOEs than for SOEs. The variable, Develop, is the index score of marketization for each province in China (Fan, Wang and Zhang 2001) which captures the development disparity of different regions.

In summary, our variable selection for equation (1) for AQD and equation (2) for EM models are very similar as most of the variables can be linked to audit quality and earnings management with some theoretical support. The two exceptions are ForeignD and Develop as we do not have a strong theoretical argument to relate them to earnings management. Therefore, we exclude ForeignD and Develop in equation (2).

4. Empirical Results

We report the descriptive statistics (mean, median, maximum, minimum, and standard deviation) of audit quality measure (AQ), earnings management proxy (EM), management demographic characteristics and other control variables for our sample firms in Table 1. Of our 3,881 observations, there are 952 and 2,929 firms employing audit firms with high quality and audit firms with low quality, respectively. These statistics are consistent with the previous studies that the audit market in China is

dominated by the government-affiliated auditors (DeFond, Wong and Li 2000; Wang, Wong and Xia 2008). There are 3,112 chairpersons holding academic or professional certification titles. The mean of years of chairpersons (Tenure) staying in office is 3.78 years. The chairpersons have an average age of 49.60 in our sample. The number of females holding positions of chairpersons is very few. In our sample, there are only 164 female chairpersons (Gender). A majority of chairpersons (Edu = 79.34%) have university degrees[63]. To save space, we use all three AQDs only in our first-stage regression analysis in Table 3, and focus on AQD2 (Top-10) for the rest of our analysis.

4.1 Distribution Analysis and Two-sample T-test Comparison

In Table 2, we use distribution analysis and two-sample t-test for measuring differences of subsamples with different levels of auditor quality (Panel A) and earnings management (Panel B). Of the five demographic characteristics, there are significant differences in the level of auditor quality (AQD2) for the chairpersons with and without certification status (Title), who stay in office for longer and shorter time period (Tenure), and who are older and younger in age (Age). Those chairpersons with titles prefer auditor with higher to lower quality. In addition, more experienced and older chairpersons prefer auditor with higher quality.

In Panel B, there are significant differences in ⏐MJAC⏐ and ⏐PMAC⏐ for the chairpersons with and without titles and university degree. The chairpersons with titles tend to be more conservative and those with university degree tend to be more

---

[63] In our sample, the number of chairpersons holding university degree is smaller than that holding professional certification. This may be due to the 10-year Cultural Revolution in China during 1966-1976. The Cultural Revolution closed down the education system for 10 years, and consequently, leading to a lack of an entire generation of university-educated individuals. However, the chairpersons can obtain their nationally accredited professional certification without going to university.

aggressive in financial reporting. Consistent with the result of Becker, DeFond, Jiambalvo and Subramanyam (1998) that there is a larger discretionary accrual reported by non-Big 6 auditors (lower audit quality) than by Big 6 auditors (higher audit quality), we find that firms hiring higher quality auditor are less aggressive in financial reporting than firms hiring lower quality auditor.

4.2 Regression Analysis

First-stage Least-square Regression (Equation 1)

The results for first-stage least-square regression model (equation 1) are reported in Table 3 respectively. In Table 3, we use three measures of audit quality (AQ), AQD1, AQD2 and AQD3, to differentiate high and low audit quality. We hypothesize that management demographic characteristics of chairperson should be related to auditor choice. In particular, we expect that the chairpersons with certification status would prefer higher quality auditors for corporate governance. Of the five demographic characteristics, we find that Title is positively related to the three measures of AQ (AQD1, AQD2 and AQD3). The positive relation indicates that the chairpersons with certification status are more likely to use high quality auditors. Therefore, the results are consistent with our hypothesis.

We include BoardSize, IndDirRatio and DirHolding as our board governance factors. Our results in Table 3 show that there is a significant and positive relation between different measures of audit quality (AQD1, AQD2 and AQD3) and IndDirRatio. This finding supports our argument that independent directors have little motivation to make risky decisions for the firms, leading to the practice of favoring safer choice, i.e., hiring high quality auditors. The coefficient on DirHolding is positively and significantly related to AQD3, indicating that firms with higher directors' ownership percentage hire higher quality auditor.

EPS, DA MB and LnAsset are included as control variables for firm performance. Datar, Feltham and Hughes (1991) suggest that high risk firms have a

higher signaling demand for audit quality. Choi and Wong (2007) suggest that firm size affects the scale, complexity and level of effort of an audit. Consistent with our expectation, the coefficients on LnAsset and MB are positively significant. In addition, the coefficient on DA is negative, implying that firms with high leverage are more likely to hire lower quality auditors.

Among our firm demographic characteristics, ForeignD and Develop are significant while NonSOED is not. As it is more likely for firms which also issue foreign shares to hire international Big 4 CPA firms as their auditors, a positive relation between ForeignD and different auditor quality measures is found. In Table 3, the coefficients on Develop are positively significant, indicating that firms in more developed regions are more likely to hire higher quality auditors.

Second-stage Least-square Regression (Equation 2)

The results for second-stage least-square regression model (equation 2) are reported in Table 4. DeAngelo (1981) argue that large audit firms have more reputation capital at stake and hence should be more resistant to management pressure not to report contract breach. There is a larger magnitude of accruals reported by lower quality auditors than by higher quality auditor (Becker, DeFond, Jiambalvo and Subramanyam 1998). In Table 4, the coefficients on AQD2 are negatively and significantly related to |MJAC| and |PMAC|.

We use Title to test if certification status is important management demography to reflect human and social resources of upper echelons in preparing financial statement using earnings management techniques. The coefficients on Title are significantly and negatively related to |MJAC| and |PMAC|, suggesting that the chairpersons with professional title are also more prudent rather than more aggressive in preparing the financial statement of their firms. The coefficient on Tenure is negatively related to |MJAC| and |PMAC|. Our finding is consistent with this conjecture that the longer the

number of years the chairpersons stay in office, the more conservative and risk averse they would become and consequently, the less likely they would use earnings management techniques.

Among the board governance factors (BoardSize, IndDirRatio and DirHolding), only IndDirRatio is found to be significantly related to the measures of abnormal accrual. We have four financial measures (EPS, DA, MB and LnAsset) as control variables (Becker, DeFond, Jiambalvo and Subramanyam 1998). DA is positively related to |MJAC| and |PMAC|, showing that the firms with high debt-to-asset ratio may need to engage in some opportunistic activities to manage reported earnings to make the firms look better. Market-to-book ratio (MB) is our measure of growth opportunity. Our result of positive relations between |MJAC| and |PMAC| with MB is consistent with the argument that there is a higher likelihood for fast-growing firms than the slow-growing firms to engage in earnings management activities to meet shareholders' expectation (Skinner and Sloan 2002).

5. Conclusion

In this study, we examine if the demographic characteristics of chairperson affect auditor choice, and whether these two factors jointly influence the firms in restricting or permitting earnings management activity. Earnings management is an issue relating to corporate governance of the firm. Weak corporate governance practice can be reflected by evidence of accounting manipulation (Beasley 1996). We focus on the role of the chairperson in permitting earnings management. It is because the chairpersons are supposed to manage the firms for the best interest of shareholders, if the management employs lower quality auditors and manipulates earnings, the information asymmetry between the inside directors and outside shareholders increases, which affects negatively the interest of shareholders.

Auditors play an important role in controlling management reporting discretion and this is also an issue relating to corporate governance. By examining the impact of management demography on auditor choice and earnings management, we provide evidence on the effectiveness of the monitoring mechanism on director behavior and corporate governance and the relation between internal and external monitoring mechanisms of the firms in China. We find that firms managed by chairpersons with titles tend to hire higher quality auditors and engage in less earnings management activity. In addition, firms with a higher percentage of independent directors tend to hire better quality auditors. Furthermore, chairpersons with titles and longer tenure conduct less earnings management.

THE EFFECTS OF STRATEGY-CONTROL SYSTEM MISFITS ON FIRM PERFORMANCE

Lindawati Gani, Universitas Indonesia
Johnny Jermias, Simon Fraser University

Abstract

The purpose of this study is to investigate the effects of misfit between business strategy and management control systems on performance. We argue that the misfit between business strategy and management control systems has significant negative implications on firm performance. Based on a questionnaire survey of 109 bank executives, we found that the strategy-control systems misfit has a significant negative correlation with performance both using financial and non-financial measures. In addition, we found that the magnitudes of differences in correlations between misfit and performance for critical-control systems are significantly more negative than the correlations between misfit and performance for non-critical control systems.

Key words: Business strategy, management control system, performance, contingency theory, systems approach.

1. Introduction

The purpose of this study is to investigate the effects of misfits between business strategy and management control systems (MCS) on performance. We argue that the misfits between business strategy and MCS have significant negative implications for performance. Specifically, we address the following research question: "Do firms that align their MCS to the specific requirements of their business strategy perform significantly better than those that do not achieve the required match?"

We conceptualize business strategy based on Miles and Snow's (1978) strategic archetypes. We use a multi-item scale approach proposed by Conant, Mokwa & Varadarajan (1990) to classify firms as defender, prospector and analyzer. Furthermore, we adapt the MCS proposed by Selto, Renner and Young (1995) and Van de Ven & Ferry (1980) which include performance evaluation, compensation, communication, conflict resolution, commitment and product and market policies. A fit is defined as the degree to which the control systems adhere to an empirically determined "ideal profile" for a given type of competitive strategy. We measure misfits using a weighted Euclidean distance from the ideal profile along the six MCS variables.

Based on a questionnaire survey of 109 bank executives, we found that the misfit between business strategy and MCS has a significant negative correlation with performance both using financial and non-financial measures. In addition, we found that the correlations between misfit and performance for critical-control systems are significantly more negative than the correlations between misfit and performance for non-critical control systems.

This study contributes to the existing literature investigating the impact of strategy and MCS on performance in four ways. First, we provide a clear operationalization of the strategy-MCS misfit by measuring a construct as a weighted Euclidean distance of a firm from the empirically determined ideal profile using the standardized beta generated by OLS regressions. Second, we demonstrate that the magnitudes of differences in correlations between misfits and performance for crucial control variables are significantly more negative than the correlations between misfits and performance for non crucial control variables. As such, our study might help firms improve their performance by focusing on factors that are crucial for them to thrive and succeed. Third, we use a broader set of management control systems than prior studies that typically focus only on performance evaluation and compensation. Fourth, we investigate a broader set of performance measures than previous studies that mostly use financial measures.

The remainder of the paper is organized as follows. Section two discusses previous related literature to develop the hypotheses. Section three explains the sample selection, research design and how to measure the variables used in this study. Section four presents the results of the statistical analyses. Section five provides the general discussions of the main results, the limitations of this study and the direction for future research in this area.

2. Related Literature and Hypotheses

There has been a considerable interest in the study of the relationship between strategy, MCS and performance. Previous research in this area can be categorized into three main streams. First, studies that investigate the impact of strategy on MCS (Quanttrone & Hopper, 2005; Langfield-Smith, 1997; Abernethy &Lillis, 1995; Abernethy & Guthrie, 1994; Dent, 1990; Simons 1987). This stream of research considers MCSs as strategy implementation systems. The basic argument is that MCS should be designed to support a firm's chosen strategy to gain competitive advantage and superior performance. Quattrone & Hopper (2005), for example, proposed that different strategies will lead to different configurations, implementations, and usage of management control systems. Other authors suggest that prospector and defender strategies require quite different design and use of MCA (e.g., Abernethy & Lillis, 1995; Abernethy & Guthrie, 1994; Langfield-Smith, 1997, Simons, 1987). Miles and Snow (1978), for example, found that a particular configuration of task technology, structure, and process is adopted by firms to match their strategy. In their study, they found that firms that adopt a defender strategy tend to adopt a functional structure with high formalization to support their capability to operate efficiently. In contrast, firms that adopt a prospector strategy tend to adopt low formalization to support their ability to create new product and exploit market opportunities. For firms that adopt an analyzer strategy, they tend to adopt a functional structure characterized by fluid product-market group to balance the pressure for innovation and efficiency.

A second stream of research examines the influence of MCS on strategy (Chenhall & Euske, 2007; Chenhall, 2005; Bisbe & Otley, 2004; Marginson, 2002; Dent, 1991). This stream of research considers MCS as systems that are used by management to formulate a firm's strategy. Chenhall and Euske (2007), for example, investigated the role of activity based cost management (ABCM) in a strategic change process. Based on their study in an Australian and a US military organization, they found that information generated from the ABCM systems is used by the organizations

to influence the planned organizational change. Naranjo-Gil and Hartmann (2007) conducted a survey of 103 Spanish public hospitals. They found that top management team use management accounting systems for strategic change. Based on a longitudinal study of a public sector entity spanning five years, Kober, Ng and Paul (2007) found that management control systems help to facilitate a change in strategy for their sample organizations. In a similar vein, Dent (1991) found that railway organizations used MCS to change their strategic orientation from a government dependent to a business oriented strategy.

A third stream of research investigates the impact of aligning strategy and MCS on performance (e.g., Sandino, 2007; Ittner, Larcker, & Randall, 2003; Simons, 1987). This perspective is based on the premise that strategy-MCS fit is achieved when the characteristics of a business strategy and control systems are joined together in a particular configuration to achieve completeness in a description of a social system (Van de Ven, 1979). As such, the performance effects of misfits should reflect the simultaneous and holistic pattern of inter-linkages between strategy and control systems (Venkatraman and Prescott, 1990).

Despite its intuitive appeal, previous studies investigating the effects of strategy-MCS misfits have reported weak and often contradictory results (e.g, Ittner, Larker & Randall, 2003; Sandino, 2007; Simons, 1987). Several authors have suggested that the link between strategy, MCS and performance is not fully understood (Chapman, 2005; Skaerbaek & Tryggestad, 2009).

Ittner, Larcker & Randall, (2003) investigated whether firm performance is positively associated with the extent to which management control systems are aligned with the firm's strategy. Based on a survey of US financial services firms, they found little support that deviation from the "ideal" profile negatively affect performance.

Sandino (2007) used a sample of US retailer to investigate the impact of strategy-MCS fit on performance. She employed four types of MCS: basic MCS (focus

503

on planning, setting standards and establishing the basic operations), cost MCS (emphasize on enhancing operating efficiencies and minimizing costs), revenue MCS (use to foster growth and customer responsiveness), and risk MCS (focus on reducing risks and protecting assets integrity). She reported that firms that match their MCS with their intended strategy outperform those that reveal a strategy-MCS mismatch.

Based on a sample of 76 firms, Simons (1987) reported that the use of tight budget goals and forecast data in control reports was positively related to performance for prospectors but not for defenders. However, the establishment of goals related to outputs and close monitoring of results were positively related to performance for prospectors but negatively related to performance for defenders. He concluded that intensive use of financial control systems is more effective for prospectors than defenders.

Some researchers have argued that the conceptual notion of strategy-MCS misfits is only understood implicitly rather than in explicit functional forms (e.g., Venkatraman & Prescott, 1990; Scherer, 1980). Venkatraman and Prescott (1990) argued that previous research has used phrases like "matched with", "contingent upon" or "congruent with" without necessarily providing precise guidelines for translating such phrases into the operational domain of empirical research and statistical tests. As such, there is a lack of general consensus regarding the conceptualization of misfits and its related empirical tests.

We conceptualize strategy based on Miles and Snow's (1978) generic strategy taxonomy which provides the richest portrayal of organizational arrangements associated with particular strategies (Dent, 1990). This typology is unique because it views the organization as a complete and integrated system in dynamic interaction with its environment (McDaniel and Kolari, 1987). Miles and Snow (1978) argued that prospector, defender, and analyzer are all viable strategies. The key dimension underlying this typology is the organization's response to changing environmental

conditions. According to Miles and Snow, defenders have narrow product-market domains and tend not to search outside their domains for new opportunities. Prospectors continually reach for market opportunities and tend to be creators of change in the industry. Analyzers are a mixture of both, operating in perhaps one relatively stable and one changing product-market domain.

MCS are conceptualized based on Van de Ven and Ferry's (1980) and Drazin and Van de Ven's (1985) notion of organizational process or control. We focus on control systems that have been used in the accounting literature namely performance evaluation, compensation, communication, conflict resolution, commitment, and product and market policy (e.g., Selto, Renner and Young, 1995; Gresov, 1989).

This study uses the holistic perspective[64] to determine the misfits between business strategy and MCS (e.g., Van de Ven, 1979; Selto, Renner & Young, 1995) and investigates the performance implications of the misfits. Ittner & Larker (2001) proposed that one key element in studying strategy and MCS is to identify the specific factors that do in fact lead to value creation. One way to identify the factors that contribute to value creation in the strategy-MCS study is to investigate the specific control systems that contribute positively to performance given a specific type of strategy. Following Venkatraman and Prescott (1990), we obtain a profile of control systems dimension for a set of high performing firms adopting a specific strategy. Any deviations from this profile will have negative performance implications.

The ideal profile can be derived either theoretically or empirically (Van de Ven and Drazin, 1985). The test for performance implication of the misfit between strategy and control system is provided by correlating the misfit with performance. A negative and significant negative correlation between misfit and performance will support the proposition that misfits negatively affect performance.

---

[64] Most early studies used selections and interactions method to define misfits. These two approaches, however, have been criticized for their inability to measure the alignment of the whole systems (e.g., Selto, Renner & Young, 1995; Van de Ven and Drazin, 1985).

Following a contingency theory, we hypothesize that firms that reveal a fit between strategy and MCS is more effective than those that do not achieve such fit (Lawrence & Lorsch, 1969). The more a firm deviates from the ideal profile, the lower will be its performance (Drazin and Van de Ven, 1985) since fit between strategy and control systems will reinforce competitiveness leading to superior performance (McDaniel and Kolari, 1987). However, the misfit between strategy and control systems will affect performance negatively only if the firm deviates from the ideal in terms of the critical control systems. Specifically, the following hypotheses will be tested:

H1a: A misfit between business strategy and the critical control systems will have a negative and significant impact on financial performance.

H1a: A misfit between business strategy and the critical control systems will have a negative and significant impact on non financial performance.

Venkatraman and Prescott, (1990) proposed that while the negative and significant correlation between misfits and performance support the notion that aligning MCS with strategy positively affects performance, it only serves as a necessary but not sufficient condition to argue convincingly for the strong relationship between misfits and performance. This is because the power of the test is unknown. To address this concern, Venkatraman and Prescott (1990) suggest developing a baseline profile using variables that were not significantly related to performance in each type of strategy. The baseline profile reflects a model where firms use control systems that are not critical in affecting the firms' performance. We expect that the relationship between the misfits in the baseline profile will not be significantly different from zero. Specifically, the following hypotheses will be tested:

H2a: A misfit between business strategy and the non critical control systems will not have a significant impact on financial performance

H2a: A misfit between business strategy and the non critical control systems will not have a significant impact on non financial performance

506

We also expect that the magnitude of the correlation between misfits and performance for critical MCS will be significantly more negative than the magnitude of the correlation between misfits and performance for non critical MCS. Specifically, the following hypotheses will be tested:

H3a: The correlations between misfits and financial performance for critical MCS are significantly more negative than the correlations between misfits and financial performance for non-critical MCS.

H3a: The correlations between misfits and non-financial performance for critical MCS are significantly more negative than the correlations between misfits and non-financial performance for non-critical MCS.

3. Research Method

3.1. Sample selection

To test the hypotheses developed in the previous section, a single industry was selected to minimize the environmental heterogeneity (Moers and Yuen, 2001). Data were collected from bank executives (directors and divisional managers) through a mail survey.[65] We contacted the senior management of all commercial banks in Indonesia that have retail banking operations asking their willingness to participate in our study. After obtaining approval from the senior management, we ask them to nominate a director in their unit who is responsible for its retail banking operations. We need to have respondents who are the policy makers since the questioners are related to the firm's strategic policies. The initial contact resulted in 150 respondents interested in this study. We sent the following materials to each respondent: a letter explaining the purpose of the study, the questionnaire, and a self addressed, stamped return envelope. To ensure that the materials reach the intended respondent, we sent the

---

[65] A pilot study was conducted before the survey was sent to the respondents. We used five bank officers to review the questionnaires. The main purpose of this pilot study is to investigate the degree of understanding and clarity of the questionnaire. As a result, some minor modifications were made to the questionnaire.

materials through a well-established courier company. We received 125 questionnaires

representing 88.3 % response rate. Sixteen respondents were excluded from further

analyses because the respondents do not have a retail banking operations[66] (eleven

responses) and do not answer all the required questions (five responses). Our final

sample consists of 109 banks.

3.2. Constructs and their measures

Strategy

Business strategy defines how a firm chooses to compete in its industry and

tries to achieve a competitive advantage relative to its competitors (Merchant and Van

der Stede, 2007). Andrews (1980) argued that a clearly defined business strategy

helps a firm allocates its resources to convert distinct competences into competitive

advantage. Miles and Snow (1978) proposed three successful organizational

strategies: defenders, prospectors, and analyzers.[67] Defenders focus on their niche

market and emphasize on high product quality and services (James & Hatten, 1995).

Defenders tend to have a narrow product lines and are less involved in product or

market development (Langfield-Smith, 1997). The critical success factors for defenders

are stable product and services, high product quality and services on existing products

and low prices (Miles and Snow, 1978). Prospectors strive to take advantage of market

opportunities by producing new products and services and are rewarded by their ability

to charge premium prices for their innovative products and services. The critical

success factors for prospectors are innovative products and services, broad range of

products and services and quick response to changing business environment.

Analyzers are characterized by their ability to take advantage of the strengths of both

the defenders and the prospectors. The key success factors for analyzers are ability to

---

[66] These respondents work either work for foreign banks or joint-venture that are not allowed to
have retail businesses.
[67] The forth type of strategy is reactor. However, since reactor is considered an unsuccessful
type of strategy (see for example Shortell and Zajac, 1990; Langfield-Smith, 1997), it is not
discussed and used in this paper.

adopt innovation, in-depth analyses for innovative products and services before adopting them, adoption of innovative products with lower prices achieved through efficiency and close monitoring of competitors' activities.

We use a multi-item scale approach to measure business strategy (see section A1 of Appendix 1). This approach has been used successfully to measure types of business strategy in previous studies (e.g., Segev, 1987; Conant Mokwa & Varadajan, 1990). Some authors (e.g., Segev 1987; McDaniel & Kolari, 1987; McKee, Vanarajan & Pride, 1989) argued that the multi-item approach is superior to self-typing method since the multi-item approach has detail questions that tend to lead the respondents to choose a particular type of strategy that is closely represent their firms' actual strategy. This approach has been acknowledged as an appropriate method when conducting strategy research (Snow & Hambrick, 1980; Huber & Power, 1985) and has been frequently used in previous studies (Snow & Hrebiniak, 1980; Smith, Guthrie & Chen, 1986; Segev 1987; McDaniel & Kolari, 1987).

The questionnaire contained a list of firms' characteristics and the respondents were asked to indicate the characteristics that best described their firm on a scale of 1 (the characteristic does not suit my firm at all) to 6 (the characteristic suits my firm to a very high degree). The respondent were informed that there is no "good" or "bad" characteristic and they were asked to indicate their actual situation. The characteristics represent Miles and Snow's (1978) strategic typology of defender, prospector, and analyzer. The terms "defender", "prospector", and "analyzer", however, were not used on the questionnaire. Rather, each description was replaced by the terms "Type 1", "Type 2" and "Type 3".

There are eighteen items used to measure strategy. The first six items in the questionnaires refers to the key success factors of defenders. Items seven to thirteen represent the key success factors of prospectors. The last five items in the questionnaire indicate the key success factors of analyzers. Following the approach

introduced by Conant, Mokwa, & Varadarajan (1987), we use the "majority-rule" decision structure to categorize firms into their strategic archetypes. Firms are classified as defenders, prospectors, or analyzers based on the highest average score of the three types of strategies. Based on this procedure, 64 respondents are classified as defender, 28 respondents are classified as prospectors and 17 respondents are classified as analyzers.　　*.Management control systems (MCS)*

MCS are put in place to ensure that employees only engage in value maximizing activities. MCS ensure that employees understand and consistently work hard to accomplish what are expected of them, they implement the firm's intended strategy, and they are capable of performing their jobs (Merchant and Van der Stede, 2007). MCS includes both formal and informal systems. Formal control systems include rules, standard operating procedures, manuals, and budgeting systems. Informal control systems are not deliberately designed but are important to achieve superior performance. Informal control systems include work ethics, management style, and organizational culture. Both formal and informal control systems influence employees' behavior and consequently affect the degree to which goal congruence can be achieved.

We adapt the MCS constructs used in previous studies (e.g., Selto, Renner & Young, 1995; Van de Ven and Ferry, 1980; Gresov, 1989; Drazin & Van de Ven, 1985). There are six variables used for the MCS: performance evaluation, compensation, communication, conflict resolution, commitment, and product and market policy. Table 1 provides the definition of these variables. We use a multi-item scale approach to measure the control system construct (see section A2 of Appendix 1). Respondents were asked to indicate whether they use a particular MCS and to rate the degree of importance attached to each system used on a 6-point Likert-type scale (1 = negligence; and 6 = significantly very important).

[Insert Table 1 here]

Performance

We investigate the performance implication of strategy-control system misfits using both financial and non-financial measures that are critical for banks to thrive and success. The financial measures consist of four variables: return on assets (ROA), return on equity (ROE), non-performing loan (NPL) and net interest margin (NIM). The non-financial measures consist of two variables: customer satisfaction and employee satisfaction. ROA is the ratio of profit to total assets. ROE is the ratio of profit to total equity. NPL is the ratio of non-performing loan to total credit. NIM is the difference between interest revenues and interest expenses. Customer satisfaction is measured based on the length of time a customer stays with the bank. Employee satisfaction is measured based on the average length of time that employees work for the bank. The abbreviated version of the questionnaires on how we measure the firm performance is shown in section A3 of appendix 1. Respondents were asked to indicate their banks' performance relative to their leading competitors. Responses were given on a 6-point Likert-type scale (1 = significantly below average; and 6 = significantly above average).

Strategy-MCS misfit

The strategy-structure misfit is measured based on the degree of departure of the observed configurations from the "ideal" configurations for a given type of strategy. Van de Ven and Drazin (1985) proposed that there are two steps to measure a misfit using a system approach. First, an ideal profile is generated from high performing organizations. Second, the sampled organizations' configurations are compared to the "ideal" profile using the Euclidean distance measures.

Following Venkatraman and Prescot (1990), we measure a misfit based on the weighted Euclidean distance of an organization from the ideal profile for a specific type of strategy. Specifically, the misfit is measured using the following formula:

$$\text{MISFIT} = \sum_{j=1} (b_j(X_{sj} - \overline{X}_{cj}))^2 \qquad (1)$$

511

Where,

> X_{sj} = the score for the organization in the study sample for the jth variable;
>
> X_{cj} = the mean score for the "ideal" profile along the jth variable;
>
> b_j = standardized beta weight of the OLS regression equation for the jth variable in the specific type of strategy;
>
> j = 1, n where n is the number of control systems variables in the specific type of strategy.

The measure of a misfit is based on the approach first introduced by Van de Ven & Drazin (1985), but has been modified by Venkatraman & Prescott (1990) to consider variables (and their relative weights) that are critically related to performance or those that are not critically related to performance for a given type of strategy.

4. Data Analysis and Result

4.1. Analytical Procedure

There are three stages used to analyze the data and test the hypotheses. In the first stage, we perform separate analyzes for each type of strategy. These analyzes include: 1) run a separate OLS regression for each performance measure (financial and non-financial measures) on the six control systems (i.e., performance evaluation, compensation, communication, conflict resolution, commitment, and product and market policy) to obtain the standardized coefficients for the MCS variables that are significantly related to performance and MCS variables that are not significantly related to performance; 2) rank-order the firms with respect to their financial (non-financial) performance; 3) consider the top 10 percent firms as the "ideal" group and the remaining 90 percent firms as the "sample" group.

In the second stage, we measure the degree of strategy-MCS misfits for both the significant variables (MISFIT_C) and the non-significant variables (MISFIT_NC) for each type of strategy. This procedure is performed separately for financial and non financial performance measures and include: 1) determine the "ideal" control systems

512

for each type of strategy based on the control systems of the high performing firms (i.e.,

top 10 percent); 2) measure the deviation from the "ideal" profile by comparing the

sample firms' MCS to the MCS of the "ideal" profile; 3) calculate the misfit for each firm

by summing the products of the deviation score of each MCS with its corresponding

standardized coefficient as shown in equation (1).

In the third stage, we correlate the misfit and performance for financial and non

financial measures. We run separate analyses for each type of strategy. We then use

z-tests to investigate whether the correlation coefficients between the MISFIT_C and

performance is significantly different from those coefficients between the MISFIT_NC

and performance. The analytical procedures are presented in figure 1.

[Insert Figure 1 here]

4.2. Statistical Analyses and Results

We begin our analyses by assessing the reliability of the constructs used in this

study. The eleven constructs and their inter-item reliability are shown in Table 2. The

results indicate that the reliability of the constructs is within the acceptable range

(Nunnally, 1967) with the minimum of 0.70 and the maximum of 0.94.

[Insert Table 2 here]

To investigate whether the multi-item questionnaires have dimensions that are

consistent with the proposed construct used in this study, we perform a principal

component factor analysis[68]. As shown in Table 3, defender has one factor (66.25 % of

the variance explained), prospector has one factor (63.34 % of the variance explained),

analyzer has one factor (60.05 % of the variance explained), performance evaluation

has one factor (84.36 % of the variance explained), compensation has one factor

(75.97 of the variance explained), communication has one factor (75.69 % of the

variance explained), conflict resolution has one factor (75.69 % of the variance

---

[68] To obtain a clear pattern of loadings, we use Varimax with Kaiser Normalization rotation
method. In applying this procedure, factors with Eigenvalues greater than 1.00 were retained.

513

explained), commitment has one factor (67.35 % of the variance explained), product and market policy has one factor (80.64 % of the variance explained), financial performance has one factor (53.12 % of the variance explained), and non financial performance has one factor (86.21 % of the variance explained). The results confirm that the questionnaires used in this study can be categorized into their intended constructs.

[Insert Table 3 here]

Table 4 reveals the Pearson correlations for all variables used in this study. The two performance variables used in this study is highly correlated ($r = 0.792$, $p < 0.001$) indicating that they measure the same construct.

[Insert Table 4 here]

Table 5 presents the descriptive statistics about the variables used in this study for defender, prospector, analyzer and total sample. The mean responses for financial performance measures are: 3.96, 3.93, 3.68, and 3.79 for defender, prospector, analyzer and total sample respectively. The mean responses for non financial measures are: 3.59, 3.55, 2.90, and 3.47 for defender, prospector, analyzer and total sample respectively. In terms of performance evaluation, the mean responses are: 3.30, 5.43, 4.88, and 4.06 for defender, prospector, analyzer, and total sample respectively. The mean responses for compensation are: 3.67, 5.20, 4.47, and 4.16 for defender, prospector, analyzer, and total sample respectively. The mean responses for compensation are: 3.67, 5.20, 4.47, and 4.16 for defender, prospector, analyzer, and total sample respectively. The mean responses for communication are: 4.96, 5.28, 5.01, and 5.05 for defender, prospector, analyzer, and total sample respectively. The mean responses for conflict resolution are: 3.39, 5.12, 4.02, and 3.91 for defender, prospector, analyzer, and total sample respectively. The mean responses for commitment are: 4.97, 3.30, 3.69, and 3.76 for defender, prospector, analyzer, and

total sample respectively. The mean responses for product and market policy are: 4.31, 4.34, 4.44, and 4.35 for defender, prospector, analyzer, and total sample respectively.

Table 5 also presents the descriptive statistics of the misfit constructs using both financial and non-financial performance measures for the crucial control systems (MISFIT_C) and non-crucial control systems (MISFIT_NC). The means of MISFIT_C for financial measures are: 1.79, 4.27, 2.22, and 2.19 for defender, prospector, analyzer and total sample respectively. The means of MISFIT_NC for financial measures are: 0.01, 0.03, 0.21, and 0.03 for defender, prospector, analyzer and total sample respectively. The means of MISFIT_C for non financial measures are: 1.13, 4.52, 2.26, and 2.04 for defender, prospector, analyzer and total sample respectively. The means of MISFIT_NC for non financial measures are: 0.01, 0.05, 0.27, and 0.04 for defender, prospector, analyzer and total sample respectively.

[Insert Table 5 here]

Table 6 present the results of the OLS regression analyses for financial performance measure as the dependent variable for each type of strategy[69]. The results indicate that performance evaluation (β = 0.440, p < 0.01), compensation (β = 0.191, p < 0.05), conflict resolution (β = 0.242, p < 0.05), and commitment (β = 0.176, p < 0.01), are significantly related to performance for defenders. For prospectors, compensation (β = -0.246, p < 0.10), commitment (β = 0.583, p < 0.01), and product and market policy (β = 0.488, p < 0.01), are significantly related to performance. For analyzers, only commitment (β = 0.777, p < 0.05) is significantly related to performance.

[Insert Table 6 here]

Table 7 present the results of the OLS regression analyses for non financial performance measure as the dependent variable for each type of strategy[70]. The results indicate that performance evaluation (β = 0.305, p < 0.05), compensation (β =

---

[69] For the sake of completeness, we also include the OLS regression for the total sample.
[70] For the sake of completeness, we also include the OLS regression for the total sample.

0.226, p < 0.10), conflict resolution (β = 0.241, p < 0.10), and commitment (β = 0.202, p < 0.05), are significantly related to performance for defenders. For prospectors and analyzers, only commitment (β = 0.750, p < 0.01; and β = 0.688, p < 0.10, respectively) is significantly related to performance.

[Insert Table 7 here]

Table 8 summarizes the results of the correlation analyses between MISFIT_C and performance and also between MISFIT_NC and performance for financial performance. It also reports the results of the test for the difference in the magnitude of the correlation coefficients[71].

Hypothesis H1a predicts that a misfit between business strategy and the critical control systems will have a negative and significant impact on financial performance. The results indicate that the misfits of strategy and the crucial control variables (MISFIT_C) have negative and significant correlations with financial performance for all types of strategy (r = -0.916, p < 0.01 for defenders; r = -0.958, p < 0.01 for prospectors; and r = -0.689, p < 0.01 for analyzer). The results are consistent with hypothesis H1a.

Hypothesis H2a posits that a misfit between business strategy and the non critical control systems will not have a significant effect on financial performance. The results reveal that the correlations between MISFIT_NC and financial performance are not significant for all types of strategy. The results confirm hypothesis H2a.

Hypothesis H3a expects that the correlation between MISFIT_C and financial performance will be significantly more negative than the correlation between

---

[71] We use the procedure proposed by Chen and Popovich (2002) to test the difference in magnitude of the correlation coefficients. The following formula is used to perform this test:

$z = \dfrac{z_{rs} - z_{rns}}{\sqrt{1/(n_s - 3) + (n_{ns} - 3)}}$ where z_{rs} and z_{rs} are the z –values of the correlation coefficients for the MISFIT_C and MISFIT_NC, respectively obtained from the following formula:

$z_r = 0.5 X \log_e \dfrac{(1+r)}{(1-r)}$.

MISFIT_NC and financial performance. The results show that the correlations between MISFIT_C and financial performance are significantly more negative than the correlation between MISFIT_NC and financial performance for all types of strategies (z = 8.495, p < 0.01 for defenders; z = 5.321, p < 0.01 for prospectors; and z = 1.984, p < 0.05 for analyzers). The results support hypothesis H3a.

[Insert Table 8 here]

Table 9 reveals the results of the correlation analyses between MISFIT_C and non financial performance and also between MISFIT_NC and non financial performance. It also reports the results of the test for the difference in the magnitude of the correlation coefficients[72].

Hypothesis H1b predicts that a misfit between business strategy and the critical control systems will have a negative and significant impact on non financial performance. The results indicate that the misfits of strategy and the crucial control variables (MISFIT_C) have negative and significant correlations with non financial performance for all types of strategy (r = -0.826, p < 0.01 for defenders; r = -0.711, p < 0.01 for prospectors; and r = -0.528, p < 0.01 for analyzer). The results are consistent with hypothesis H1a.

Hypothesis H2b posits that a misfit between business strategy and the non critical control systems will not have a significant effect on non financial performance. The results reveal that the correlations between MISFIT_NC and non financial performance are not significant, except for prospectors where the correlation is negative and significant (r = -0.209, p < 0.05). The results provide some support to hypothesis H2a.

Hypothesis H3b expects that the correlation between MISFIT_C and non financial performance will be significantly more negative than the correlation between

---

[72] We use the same procedure to test the difference in magnitude of the correlation coefficients as discussed earlier for financial performance.

MISFIT_NC and non financial performance. The results show that the correlations between MISFIT_C and non financial performance are significantly more negative than the correlation between MISFIT_NC and non financial performance for defenders and prospectors ($z = 5.927$, $p < 0.01$ and $z = 2.194$, $p < 0.05$ respectively). For analyzers, however, the correlation difference is not statistically significant. The results provide some support to hypothesis H3b.

[Insert Table 9 here]

5. Discussions, Limitations, and Implications for Future Research

The notion of strategy-control system misfits is a central theme in management accounting research utilizing a contingency approach and the performance implications of strategy-control system misfits are intuitively appealing. However, little research has been conducted to support this proposition. In particular, no studies have considered using relative weights of different control systems. This is important since the notion of equal weight is generally considered untenable.

In this study, we derive the weights by performing OLS regressions and use the standardized beta weights of the regression equation of control system variables on performance for each type of strategy. The results indicate that the strategy-control system misfit for crucial control system variables has a significant negative effect on performance. By contrast, the strategy-control system misfits for non-crucial control system variables do not affect performance negatively (except for the marginally significant effect on performance for prospectors when non-financial measures of performance are used as the dependent variable). More importantly, the magnitude of the correlations between misfits and financial performance for the crucial control variables are significantly more negative than the correlations between misfit and performance for the non-crucial control variables for all types of strategies. Furthermore, the correlations between misfit and non-financial performance for crucial control variables are more negative than those for non crucial control variables. The magnitude

518

of the differences of the two correlations, however, is only statistically significant for the defender strategy.

It is interesting to note that not all of the correlations between misfits and performance for the non-crucial control systems are close to zero. As shown in Table 9, the correlation between misfit and non-financial performance for the non-crucial control variables is negative and marginally significant for prospectors. This unexpected result has two implications. First, deviation from the ideal profile in terms of non-crucial control system could have a negative and significant impact on performance. Second, there is the need to compare between the magnitude of correlations between misfits and performance for the critical and non-critical control systems to provide evidence that the misfits in terms of crucial control variables are more damaging than the misfits in terms of non-crucial control variables. As such, our study might help firms improving their performance by focusing the deployment of their limited resources on control systems that are crucial for the companies to thrive and succeed, given their chosen strategy.

The results of this study should be interpreted in light of three limitations. First, the misfit construct was derived empirically by comparing the control systems used by high performing firms and those of the sample firms. It might be that the high performing firms use control systems that are not consistent with the theoretical prescriptions of the strategy-control system fit. However, the theoretically derived "ideal profile" is still debatable and the operational task of specifying such profile with numerical scores along a set of MCS is a difficult task (Venkatraman & Prescott, 1990). We leave this for future research.

Second, we use data from banking industry which is known for its highly regulated and tight government control. Future studies might use data from different industry to enhance the generalizability of our results.

519

Finally, the data used in this study are collected using a questionnaire survey. While this approach enables us to explore the richness of the reality by soliciting inputs directly from the executives responsible for designing and implementing the firms' strategy and control systems, socially responsible bias due to subjective responses to the questionnaires should be taken into considerations when making inferences about the results of this study.

Table 1
Definitions of management control system constructs

Constructs	Definition
Performance evaluation	Employees' performance evaluation systems that encourage employee development and motivation
Compensation	The degree to which employees' compensation are contingent on performance
Communication	The ability of top management to communicate the firm's vision, mission and objectives to the stakeholders honestly, openly, and systematically
Conflict resolution	The ability of top management to anticipate and solve conflicts between units/elements in the firm
Commitment	The degree of top management' commitment and their ability to gain commitment from the whole employees to realize the firm's vision, mission and objectives
Product and market policy	The ability of a firm to provide products and services to satisfy customers' demand

Table 2
Inter-item construct reliability

Constructs	Cronbach Alpha
Defender	0.77
Prospector	0.90
Analyzer	0.83
Financial performance	0.70
Non-financial performance	0.84
Performance evaluation	0.81
Compensation	0.83
Communication	0.92
Conflict resolution	0.92
Commitment	0.77
Product and market policy	0.94

Financial consists of four financial performance measures: return on asset, return of equity, net interest margin and non-performing loan. Non financial consists of two non-financial measures: customer satisfaction and employee satisfaction. Performance evaluation is the employees' performance evaluation systems that encourage employee development and motivation. Compensation is the degree to which employees' compensation is contingent on performance. Communication is the ability of managers to communicate the firm's vision, mission and objectives to the stakeholders honestly, openly, and systematically. Conflict resolution is the ability of management to anticipate and solve conflicts between units/elements in the firm. Commitment is the degree of top management commitment and their ability to gain commitment from the whole employees to realize the firm's vision, mission and objectives. Product and market policy is the ability of a firm to provide products and services to satisfy customers' demand

Table 3
Results of factor analyses on strategy, control systems and performance

Factor	Eigenvalue	Percent of variance explained
Defenders	3.98	66.25
Prospectors	4.43	63.35
Analyzers	3.00	60.05
Performance evaluation	1.69	84.36
Compensation	2.28	75.97
Communication	3.79	75.69
Conflict resolution	3.78	75.69
Commitment	3.37	67.35
Product and market policy	4.03	80.64
Financial performance	2.13	53.12
Non-financial performance	1.72	86.21

Financial consists of four financial performance measures: return on asset, return of equity, net interest margin and non-performing loan. Non financial consists of two non-financial measures: customer satisfaction and employee satisfaction. Performance evaluation is the employees' performance evaluation systems that encourage employee development and motivation. Compensation is the degree to which employees' compensation is contingent on performance. Communication is the ability of managers to communicate the firm's vision, mission and objectives to the stakeholders honestly, openly, and systematically. Conflict resolution is the ability of management to anticipate and solve conflicts between units/elements in the firm. Commitment is the degree of top management commitment and their ability to gain commitment from the whole employees to realize the firm's vision, mission and objectives. Product and market policy is the ability of a firm to provide products and services to satisfy customers' demand

Table 4: Pearson Correlations among Variables (n=114) (P-values in Parenthesis)

Variable	Financial	Non-financial	Performance evaluation	Compensation	Communication	Conflict resolution	Commitment	Product and market policy
Financial	1							
Non-financial	0.792 (0.000)	1						
Performance evaluation	0.570 (0.000)	0.452 (0.000)	1					
Compensation	0.520 (0.000)	(0.427 (0.000)	0.829 (0.000)	1				
Communication	0.032 (0.732)	0.103 (0.278)	0.139 (0.140)	0.228 (0.015)	1			
Conflict resolution	0.643 (0.000)	0.536 (.000)	0.821 (0.000)	0.734 (0.000)	0.140 (0.138)	1		
Commitment	0.670 (0.000)	0.578 (0.000)	0.136 (0.149)	0.130 (0.168)	-0.024 (0.796)	0.274 (0.003)	1	
Product and market policy	0.265 (0.004)	0.201 (0.032)	0.093 (0.324)	0.042 (0.657)	0.468 (0.000)	0.112 (0.236)	-0.830 (0.000)	1

Financial consists of four financial performance measures: return on asset, return of equity, net interest margin and non-performing loan. Non financial consists of two non-financial measures: customer satisfaction and employee satisfaction. Performance evaluation is the employees' performance evaluation systems that encourage employee development and motivation. Compensation is the degree to which employees' compensation is contingent on performance. Communication is the ability of managers to communicate the firm's vision, mission and objectives to the stakeholders honestly, openly, and systematically. Conflict resolution is the ability of management to anticipate and solve conflicts between units/elements in the firm. Commitment is the degree of top management commitment and their ability to gain commitment from the whole employees to realize the firm's vision, mission and objectives. Product and market policy is the ability of a firm to provide products and services to satisfy customers' demand.

Adjusted R-squared	0.812	0.890	0.610	0.706
Sample size	58	25	15	98

[a] The coefficients are reported in the standardized form.
[b] *, **, *** denote significance level at 0.10, 0.05, and 0.01 based on two-tailed tests.
The dependent variable is financial performance measure which consists of return on assets, return of equity, net interest margin and non-performing loan.
Performance evaluation is the employees' performance evaluation systems that encourage employee development and motivation. Compensation is the degree to which employees' compensation is contingent on performance. Communication is the ability of managers to communicate the firm's vision, mission and objectives to the stakeholders honestly, openly, and systematically. Conflict resolution is the ability of management to anticipate and solve conflicts between units/elements in the firm. Commitment is the degree of top management commitment and their ability to gain commitment from the whole employees to realize the firm's vision, mission and objectives. Product and market policy is the ability of a firm to provide products and services to satisfy customers' demand.

Table 7:
OLS of management control systems on non-financial performance in each type of strategy

Control variable	Defender Coefficient (t-statistic)	Prospector Coefficient (t-statistic)	Analyzer Coefficient (t-statistic)	Total sample Coefficient (t-statistic)
Intercept	- (-1.909)*	- (1.801)*	- (-0.466)	- (-1.318)
Performance evaluation	0.305 (2.064)**	0.108 (0.510)	-0.204 (-0.586)	0.097 (0.647)
Compensation	0.226 (1.859)*	-0.168 (-0.647)	0.284 (0.692)	0.096 (0.746)

Adjusted R-squared	0.672	0.548	0.336	0.475
Sample size	58	25	15	98

[a] The coefficients are reported in the standardized form.

[b] *, **, *** denote significance level at 0.10, 0.05, and 0.01 based on two-tailed tests. The dependent variable is non financial performance measure which consists of customer satisfaction and employee satisfaction. Performance evaluation is the employees' performance evaluation systems that encourage employee development and motivation. Compensation is the degree to which employees' compensation is contingent on performance. Communication is the ability of managers to communicate the firm's vision, mission and objectives to the stakeholders honestly, openly, and systematically. Conflict resolution is the ability of management to anticipate and solve conflicts between units/elements in the firm. Commitment is the degree of top management commitment and their ability to gain commitment from the whole employees to realize the firm's vision, mission and objectives. Product and market policy is the ability of a firm to provide products and services to satisfy customers' demand.

Table 8:
Correlations between misfit and financial performance in each specific strategy: Misalign vs. Baseline

Type of strategy	Sample[c]	Misalign - financial performance (A) Coeeficient[a,b]	Baseline – financial performance (B) Coeeficient (t-statistic)	z-test between (A) and (B)[d] Coeeficient (z-statistic)
Defender	58	-0.916***	-0.036	8.495***
Prospector	25	-0.958***	-0.272	5.321***
Analyzer	15	-0.689***	-0.105	1.984**

[a] Pearson's correlation coefficients..
[b] *, **, *** denote significance level at 0.10, 0.05, and 0.01 based on two-tailed tests.
[c] The sample size reflects the total sample in a specific type of strategy minus 10% for generating the "ideal" portfolio.
[d] Differences in the correlation coefficients is tested based on a z-test proposed by Chen and Popovich (2002)..

Table 9:
Correlations between misfit and non-financial performance in each specific strategy: Misalign vs. Baseline

Type of strategy	Sample[c]	Misalign – nonfinancial performance (A) Coeeficient[a,b]	Baseline – nonfinancial performance (B) Coeeficient (t-statistic)	z-test between (A) and (B)[d] Coeeficient (t-statistic)
Defender	58	-0.826***	-0.084	5.927***
Prospector	25	-0.711***	-0.209*	2.194**
Analyzer	15	-0.528**	-0.113	1.111

[a] Pearson's correlation coefficients..
[b] *, **, *** denote significance level at 0.10, 0.05, and 0.01 based on two-tailed tests.
[c] The sample size reflects the total sample in a specific type of strategy minus 10% for generating the "ideal" portfolio.
[d] Differences in the correlation coefficients is tested based on a z-test proposed by Chen and Popovich (2002)..

A.1. Strategy

---

* The analytical procedure is adapted from Venkrataman and Prescott (1990).

Which of the following descriptions most closely fits your bank compared to other banks in the industry (1 = the characteristic does not suit my bank at all; 6 = the characteristic suits my bank to a very high degree). Please consider your bank as a whole and note that none of the types listed below is inherently "good" or "bad".

Type1:
Q1: This bank tries to locate a safe niche in a relatively stable products domain.
Q2: The bank tends to offer a more limited range of products or services than its competitors.
Q3: The bank tries to protect the environment domain in which it operates by stressing higher quality than its competitors.
Q4: The bank concentrates on trying to achieve the best performance in a relatively narrow product-market domain.
Q5: The bank places less stress on the examination of changes in the industry that are not directly relevant to the bank.
Q6: The bank tries to maintain a limited line of products and tries to maintain a stable line of products.

Type 2:
Q1: This bank leads in innovations in its industry
Q2: The bank operates in a broad product domain.
Q3: The bank product domain is periodically redefined.
Q4: The bank's believes in being "first in" in the industry in development of new products.
Q5: Not all the bank's efforts invested in being "first in" in the industry in development of new products proved to be profitable.
Q6: The bank responds rapidly to early signals of opportunities in the environment
Q7: The bank's actions often lead to a new round of competitive activity in the industry.

Type 3:
Q1: The bank adopts quickly promising innovations in the industry.
Q2: The innovations which are chosen by the bank are carefully examined.
Q3: The bank often reacts to innovations in the industry by offering similar, lower cost products.
Q4: The bank carefully monitors competitors' actions in the industry.
Q5: The bank only seldom leads in developing new products in the industry.

A2: Management control systems

Please indicate your banks' performance relative to its leading competitors (1 = significantly below average; and 6 = significantly above average).

Performance evaluation:
Q1: The bank evaluates its employees based on their target achievements that have been agreed upon.
Q2: The bank evaluates its employees periodically
Compensation:
Q1: The bank uses compensation systems that are linked to performance
Q2: The bank gives its employees incentive compensations besides their salary.
Q3: The bank measures employee satisfaction periodically

Communication:

Q1: The management of this bank communicates with the employees honestly and openly.
Q2: The management of this bank communicates with the employee clearly and confidently.
Q3: The management of this bank communicates their ideas systematically.
Q4: The management of this bank listens and responds to subordinates' ideas and opinion appropriately.
Q5: The management of this bank maintains two-ways communication systems.

Conflict resolution:
Q1: The management of this bank manages internal conflicts positively and constructively.
Q2: The management of this bank always attempts to solve conflicts through a win-win solution.
Q3: The management of this bank always tries to ensure that a conflict will not have a negative impact personally.
Q4: The management of this bank has negotiation skills to solve conflicts
Q5: The management of this bank has the ability to think about the long term relationships in conflict resolutions

Commitment:
Q1: The management of this bank is highly committed to achieve the objective of this bank.
Q2: The management of this bank encourages all elements of the bank to have a high commitment on achieving the bank's objectives
Q3: To increase commitment, the management of this bank is flexible in setting targets and in allocating resources.
Q4: The management of this bank shares ideas and values to gain employees' commitment.
Q5: The management of this bank encourages their employees to translate commitment into accountability

Product and market policy:
Q1: The bank provides products and services demanded by its customers.
Q2: The bank tries to develop new products and services and invests in research and development projects.
Q3: The bank analyzes its pricing of products and services periodically
Q4: The bank invests in customer information systems.
Q5: The bank performs marketing research

A3: Performance

Please indicate your bank's performance relative to its leading competitors (1 = significantly below average; and 6 = significantly above average).

Financial performance:
Q1: ROA (the ratio of profit to total assets)
Q2: ROE (the ratio of profit to total equity)
Q3: NPL (the ratio of non-performing loan to total credit)
Q4: NIM (the difference between interest revenues and interest expenses)

Non-financial performance:
Q1: Customer satisfaction (the length of time a customer stays with the bank)
Q2: Employee satisfaction (the average length of time that employees work for the bank)

2.3 Earnings Management

REPORTING COMPREHENSIVE INCOME AND MANAGERIAL BEHAVIOR IN JAPAN

Miho Nakamura
Oita University

Abstract

   For the last several years, the financial performance reporting project has been one of the controversial matters for accounting standard-setters. In this paper we will examine the manipulation of net income by realizing other comprehensive income items with actual other comprehensive income numbers before and after reporting comprehensive income in Japan. We lead the following conclusions.

   Soon after introducing comprehensive income reporting, there is no significant decrease in earnings management to net income by using other comprehensive income. These days, however, we can find some statistically significant evidence for it. Therefore, we can conclude that it took time for FAS130 to function well as an expected standard-setter. In other words, a certain time was necessary for managers to recognize that the extent of transparency for financial reporting was changed by FAS130.

1. Introduction and Summary

   For these several years, the financial performance reporting project has been one of some controversial matters for accounting standard-setters. UK accounting standard-setters (ASB) leased FRS3 in 1992 and required to report all gains and losses in income statement, in the USA FASB proposed FAS130 in 1997 and decided to report comprehensive income in income statement[73]. Internationally, IASB leased IAS1 (revised), G4+1 published their special report in 1999. In 2009 the discussion paper *'Preliminary Views on Financial Statement Presentation'* was published under the name of both IASB and FASB.

   In Japan, the standard-setter has been arguing for financial performance reporting, too. Because many countries already decided to adopt FRS as their domestic accounting standard and a lot of Japanese companies are financing in Europe and other foreign countries.

   The purpose of the reporting financial performance project is to improve the format of the financial statements in order to enhance its transparency for capital providers[74]. But originally, it was to reconstruct the presentation of the income statement for improving its transparency by preventing earnings managements for net income and then to enhance investors' ability for predicting future cash flow. In other words, standard-setters presumed that the reliability of net income was reducing because of increase of earnings management at that time. And some standard-setters tried to mitigate this problem by introducing comprehensive income statement.

---

[73] Precisely, FASB introduced comprehensive income statement in FAS130. Comprehensive income is defined as net income + other comprehensive income. Other comprehensive income includes unrealized gains and losses related to exchange translation differences on foreign currency net investment, available-for-sale securities and cash flow hedged derivatives.

[74] IASB and FASB (2008).

Considering this as background, most of the early empirical researches on reporting financial performance were value-relevance style researches and they concluded that the value-relevance of net income was stronger than that of comprehensive income. On the other hand, there are few researches which analyzed the relation between comprehensive income reporting and earnings management for net income. Thinking of it, the open question whether comprehensive income reporting functions as it is expected or not still remains.

2. Review

There are several researches on the relation between earnings management and reporting comprehensive income[75].

These researches provided evidence that comprehensive income is less likely to be affected by earnings management than net income. However, we can say there are still some open questions. The reasons are as follows.

First, most of these researches include comprehensive income and its components that are calculated artificially, not ones that are titled in income statement as they are. There is a possibility that managers behave in the same way if the reporting format of financial statement does not change substantively. Considering this, these research results do not reflect the change of managers' behavior even if it happens. Second, they focused only on net income and comprehensive income, not on the relation between them－other comprehensive income. To consider whether comprehensive income reporting works as standard-setters expected, it is necessary to analyze earnings management for net income－more specifically, the relation between other comprehensive income and net income. Therefore this implies that it is still unclear how managers manage net income by controlling other comprehensive income after introducing comprehensive income reporting. The original purpose of the reporting financial project is to improve the transparency of reporting financial performance and to prevent earnings management for net income. In this respect, whether the effect of introducing comprehensive income reporting works well or not is still not clear.

3. The Relation between Other Comprehensive Income and Net Income

Generally, there are two types of earnings management. One is changing accounting policies for manipulating earnings. The other is changing business activities or contracts and then managing earnings.

Thinking of the relation between other comprehensive and net income, we will need to consider the latter type. That is, if managers want to increase or decrease their net income, they will turn other comprehensive income items (=unrealized gains) into realized gains and losses by selling available-for-sale securities, subsidiaries abroad or settling cash flow derivatives, etc.

Some of the researches above pointed out that managers have motivation for managing net income by realizing other comprehensive income. However, the previous researches above do not analyze this behavior of managers by using actual other comprehensive income numbers. Therefore, in this paper we will examine the manipulation of net income by realizing other comprehensive income items with actual other comprehensive income numbers before and after introducing reporting comprehensive income reporting.

---

[75] Hirst et al.(1998), Hutton et al.(2004), Lee et al.(2004), Satoh and Nakagawa(2006) and Wakabayashi(2006).

4. Samples and Research Hypothesis

(1) Samples

In this research, samples firm years are selected according to criterions as follows.

① Firms in Tokyo stock exchange group 1st section adopting SEC standards.

② The period for the analysis is from 1995 to 2007. Comprehensive income reporting was introduced from 1999 substantially in sample firms.

③ Firm years when total asset, net income, unrealized gains and losses related to sale available security and its reclassification[76] item are available in the annual reports during 1995~2007.

④ Firm years when unrealized gain and losses on exchange translation differences on foreign currency net investment and its reclassification is available in annual reports during 1999-2007.

⑤ Firm years when unrealized gains and losses on cash flow hedge derivatives and its reclassification is available in annual report during 2002-2007.

⑥ Inputting these samples with manual procedure

(2) Research Hypothesis

If managers think the transparency of financial performance is enhanced by comprehensive income reporting, it is presumed that the manipulation of net income by using other comprehensive income decreases after the period when introducing the comprehensive income reporting. Especially, according to FAS130, it was expected that the introduction of reporting comprehensive income would improve the traceability from other comprehensive income to net income (=recycling or reclassification).

Considering these aspects, more specifically, we present the following hypotheses.

H: the magnitude of earnings management for net income by using other comprehensive income items scales down after the period when adopting comprehensive income reporting.

(3) Research Model

We examine the hypothesis by the following two methods.

① **T-test for the average of reclassification items(=realized gains and losses)related to other comprehensive income**

We calculated the percentage of the reclassification of available-for-sale-securities in net income ($Av1_i$), turned the numbers to absolute value and conducted the t-test whether the difference($|Av1_i - Av1_{i-1}|$) of the averages was statistically significant or not after period when comprehensive income reporting was introduced(1999~2007). Additionally for the period of 1999~2007, we also conducted the same test for the reclassification of exchange translation differences on foreign currency net investment ($|Av2i - Av2i-1|$), and during the years 2002~2007 for the reclassification of cash flow hedge derivatives ($|Av3_i - Av3_{i-1}|$).

$Av1_i$=|reclassification of available-sale-security i|/|net income $_i$|
$Av2_i$=|reclassification of exchange translation differences on foreign currency net investment $_i$|/|net income $_i$|

---

[76] Reclassification is a procedure in which other comprehensive income items, when turned into realized items, are charged to net income from other comprehensive income.

$Av3_i = |$ reclassification of cash flow hedge derivatives $i|/|$net income $_i|$

      Av: average, i: firm year

② **Multiple linear regression analysis**

  As an additional examination for robustness, we conducted multiple linear regression analysis considering the factors that are presumed to affect the reclassification of other comprehensive income items.

Model: $Yit = \alpha_0 + \alpha_1 LVit + \alpha_2 PBRit + \alpha_3 D1it + \alpha_4 D2it + \alpha_5 YD1it + \varepsilon it \cdots ①$

       $Yit = \alpha_0 + \alpha_1 LVit + \alpha_2 PBRit + \alpha_3 D1it + \alpha_4 D2it + \alpha_5 YD2it + \varepsilon it \cdots ②$

    $Yit = \alpha_0 + \alpha_1 LVit + \alpha_2 PBRit + \alpha_3 D1it + \alpha_4 D2it + \alpha_5 YD3it + \varepsilon it \cdots ③$

Yit: |reclassification of available-for-sale-securities $_i|/|$net income $_i|$ of firm$_i$ in year$_t$

LV: liability to equity ratio

PBR: Price to book ratio

D1: if net income is negative or decreased (more than 30% decrease over the previous year), 1. otherwise 0.

D2: if there is more than 20% difference between reported net income and forecasted income, then 1; otherwise 0.

YD1: if 1995~1998, then 0; otherwise 1

YD2: if 1995~2004, then 0; otherwise 1

YD3: if 1999~2004, then 0; otherwise 1

εit: disturbance term

  If the liability to equity ratio is high, it can be expected that managers tend to increase earnings in order to decrease interest rate or to borrow more (loans, etc…). On PBR, if the firm's growth potential is high, managers try to increase earnings in order to make it look like their firm keeps growing. When earnings are negative, decrease or have a large difference between its forecasted income, it is presumed managers tend to increase earnings. YD1, YD2, YD3 are dummy variables to examine whether there is a difference of earnings management by other comprehensive income items before and after introducing reporting comprehensive income.

5.　Results and Implication
(1) Results form t-test

  Figure 1 shows that before introducing comprehensive income reporting (1995~1998), the average of reclassification related to available-for-sale-securities is 18.702. On the other hand, after adopting comprehensive income reporting, the average is 12.567. And the difference between them is statistically significant (5%). This result suggests that there is a possibility that the adoption of reporting comprehensive income affects the magnitude of earnings management with available-for-sale-securities and managers do not manipulate net income as much as before[77].

---

[77] It is conceivable that the tendency of reclassification of available-sale-security is influenced by the stock market trend. Then we examined it by analyzing the relation between the reclassification of available-sale-security per share and the average of Nikkei. The result is that the correlation coefficient is 0.11 and t-value is 0.382. Consequently, we conclude there is no strong relation between them.

Figure 2 presents the direction of earnings management by available-for-sale-securities. We sort out the reclassification of available-for -sale-securities per total asset each year into two categories, a positive and negative category, and accumulate each category each year. According to Figure 2, it is implied that ,except between 1999 and 2003, earnings managements in order to increase income are conducted more often.

Then, for analyzing the trend of the earnings management, we separate the examination period into three parts－1999~2001, 2002~2004, 2005~2007, and compare the average of the reclassification of available-for-sale-securities in each period with one in 1995~1998, the period in which had not adopted comprehensive income reporting.

The result is presented in Figure 3. First, the average in1999~2001 is very close to the one in 1995~1998 in Figure 1. Second, the average in 2002~2004 is less than in 1995~1998, but the difference between them is not statistically significant. On the contrary, the average in 2005~2007 is 6.704 and the difference is statistically significant (1%). This implies that soon after introducing comprehensive income reporting, managers did not care about it so much, but gradually got to be conscious of the change and restrained themselves from manipulating net income by managing available-for-sale-securities[78].

Additionally, we conducted the same examination including the reclassification of exchange translation differences on foreign currency net investment and cash flow hedge derivatives in 2002~2007 and compared to the average in 1999~2001. The implication form the result was almost the same as Figure 4 shows.

(2) Results and implications from the multiple linear regression analysis
Figure 5, 6 and7 show the results form the multiple linear regression analysis. First, as the previous researches implied, when firms have a high leverage ratio, negative or less net income, managers tend to sell available-for-sell-securities to manage net income. The result is the same when firms have a large difference between forecasted net income and reported one. Second, from figure 5 and 6, in the beginning of the period when comprehensive income reporting is introduced, there is no statistically significant change for the reclassification of available-for-sale-securities, but after 2005 it is presumed that there is decreasing of earnings management for net income, because the coefficient of YD2 is negative and statistically significant (1%).

Figure 7 presents the result from the analysis that includes reclassification of exchange translation differences on foreign currency net investment and cash flow hedge derivatives. In this analysis, it is implied that managers restrain manipulation of net income by using other comprehensive income items, because the coefficient of YD3 is negative and statistically significant (5%).

6. Conclusion
From the analysis above, we can draw these conclusions and implications.

Firstly, when leverage is high or earnings are negative or less than previous year, managers tend to manipulate earnings by using other comprehensive income items, but the magnitude is getting smaller lately.

Secondly, soon after introducing comprehensive income reporting, there is no significant decreasing of earnings management by using other comprehensive income,

---

[78] For testing its robustness, we conducted the same examination using total asset instead of net income. The result was the same.

but these days we can find some statistically significant evidences for it. Therefore, we can conclude that it took time for FAS130 to function well as standard-setter expected. In other word, managers needed time to recognize that the extent of transparency for financial reporting was changed by FAS130.

However, we cannot deny that there are some limitations to these conclusions. Our samples are Japanese firms which adopt SEC standard in 東証一部. Besides, we need to distinguish discretionary parts from non-discretionary parts more precisely in order to get more accurate results.

THE EFFECT OF CORPORATE NAME
CHANGES ON THE EARNINGS MANAGEMENT IN KOREA

Soon Suk Yoon[79], Min Kyong Park[80]

Abstract

Recently, corporate name changes by loss-reporting firms are increasing among the KOSDAQ market firms.

We first examine the current trend of and reasons for corporate name changes. Second, we examine empirically whether name change firms are associated with particular patterns of discretionary accruals. We divide the reasons for corporate name changes into cosmetic change, industry change, and largest stockholder change to examine whether there are differences in earnings management practices. From a sample of 401 name change firms over the period of 2004 to 2008, we find that bad operating performance is followed by corporate name changes. Many of the firms changing their names are plagued by embezzlements or financial fraud by management. Also many of the firms changing corporate names are administrative issues in the KOSDAQ market. Some firms change their names following major structural changes like industry change, CEO change or largest stockholder change. We find that name changes are negatively related with discretionary accruals, particularly when they change names due to accumulated losses.

Our study adds to the literature in the sense that it is the first attempt to examine the characteristics of firms changing their names and to investigate the impact of corporate name changes on discretionary accruals.

Keywords: corporate name change, loss-reporting firms, earnings management.

[79] Professor, Chonnam National University (E-mail: yoonss@chonnam.ac.kr)

[80] Ph.D. Candidate,, Chonnam National University (E-mail: cake9@hanmail.net)

1. Introduction

Recently, the financial press reports the trend that increasing number of firms change their names. Twenty four KOSDAQ firms have changed their names twice in a year and three firms have changed their names up to five times over the period of 2004 to 2008.

Corporate name is supposed to serve as a signal to convey information about a firm's major business or product lines. Investors will be better served as long as corporate names can be associated with major businesses or product lines.

According to the Korea Exchange, about one eights of KOSDAQ firms have changed their names in 2008. Why do they change their names despite non-trivial cost associated with name changes? The value of a firm would be increased if corporate name change positively conveys the plan of real changes in the firm's business activities, restructuring or reorganization.

Facing the rapid increase in corporate name changes, investors are advised to exercise caution when they make investment decisions in the firms which change their names, particularly when they purchase the securities of name change firms to disguise accumulated losses. According to our investigation, there is a big increase in corporate name changes by loss-reporting firms even though it is accompanied by non-trivial costs such as consulting fees and corporate identity costs.

Some of firms changing their names are involved in litigations such as fraud or embezzlement. Some of them are administrative issues in the KOSDAQ market. Some of them change their names following the largest stockholder changes. Especially, firms for which the largest stockholders are changed more than twice a year are designated as firms that need a special attention.

The KOSDAQ market has some features that can be distinguished from the KSE market. KOSDAQ firms are smaller and younger than KSE firms. The disclosure environment of the KOSDAQ market is inferior to the KSE. As a result, we believe the information asymmetry in the KOSDAQ would be worse than the KSE.

Yoon (2005) finds that KOSDAQ firms tend to manage earnings more aggressively than KSE firms. So there is an increasing concern on the reliability and transparency of the financial statements of KOSDAQ firms.

We find that corporate name changes in the KOSDAQ market are more frequent than in the KSE market, particularly there is a big increase in KOSDAQ market. The

announcements of corporate name changes in KOSDAQ have started since 2000 and they have announced reasons of changing definitely since 2007. The KOSDAQ market have enforced that firms changing name frequently should announce the details to prevent investors' confusion whether they had changed corporate name within 2 years since 2007 and it's one part of announcements management consolidation.

The prior literature of corporate name changes is almost about the relationship between corporate name change and stock price but they are scarce and the results in Korea are inconclusive. In this paper, we examine the purpose of the managements who change corporate name, different from the prior study. We first examine the current trend of corporate name change; how many firms have changed corporate names, how they have changed, why they change and who change corporate name. Second we examine empirically whether corporate name change firms are associated with discretionary accruals. We further divide the reasons of corporate name change into cosmetic change to hide negative earning, industry change or consolidation and change of the largest stockholders and examine whether there are differences among the corporate name change reasons.

Our study adds to the literature in the sense that it is the first attempt to examine the characteristics of firms changing their names and to investigate the impact of corporate name changes on discretionary accruals. We expect that our empirical results can play a role for the investors to let them know about corporate name changes by loss-reporting firms which increasing recently.

2. Background and Hypothesis Development

2. 1. Background

Most of the prior study about corporate name changes is about the relationship between corporate name change and stock price. Previous studies have shown mixed results about corporate name changes and valuations.

Song(1991) studied the stock price reactions to corporate name change announcements of 74 announcements for the period from 1980 to 1990. He found that weak positive stock price reaction to the announcement and he also suggests that findings are sensitive to sample selection.

Some suggests that the valuation effects of name changes are only modest and transitory. Horsky and Swyngedouw(1987) studied the effect of corporate name change on profit performance of firms and the type of firms that have a positive effect. They rightly conclude that the act of name change per se do not enhance the demand for firms' products.

Howe(1982) found that there is no significant share-price reaction was associated with corporate name changes. Also Karpoff and Rankined(1994) find little evidence that corporate name changes corresponded to changes in a firm's stock return covariability with its industry index or with changes in the firm's earnings growth rate. On the subject of fashions in naming, Cooper, Gulen and Rau(2005) examine whether or not mutual funds change their names to take advantage of currently popular investment styles, and what effects such name changes have on inflows to the funds and on the funds' subsequent returns. They report that funds adopting fashionable names experience an average cumulative abnormal inflow of 28%, with no improvement in performance, the year after such a change.

Overall, prior studies suggest that corporate name change affects stock prices in short-term, but it has no effects on firms' performance.

2. 2. Hypothesis development

The disclosure environment of the KOSDAQ market is inferior comparing the KSE. So there is an increasing concern on the reliability and transparency of the financial statements of KOSDAQ firms.

Yoon (2005) finds that KOSDAQ firms tend to manage earnings more aggressively than KSE firms. Na(1996) finds that loss-reporting firms have an incentive to lower accruals. We believe corporate name changes by loss-reporting firms will lower their earnings because most of them are administrative issues or have high debt-ratio so they couldn't manage earnings upward. We find that most of firms changing their names report current loss and have high leverage. According to the previous study and our investigation, we believe that corporate name change firms have incentives to manage earnings to disguise accumulated losses, so we set our first hypothesis as follow:

H1: There is a relationship between the corporate name change firms and earnings management.

Based on Hypothesis 1, we examine empirically the difference in reasons for corporate name changes. According to the previous study, the reasons for corporate name changes could be due to show expanded product offerings and strategic direction, to reflect company diversification and expansion, to provide a more universally representative name, and to reflect new identity following a change in ownership.

So we partition the reasons for corporate name changes into the cosmetic name change, industry change and largest stockholders change. We examined foreign ownership or export proportion to figure out firms changing their name for globalization. But we find that foreign ownership or export proportion have decreased rather following corporate name changes and we think there is a probability of misjudgment how much increase is enough to change their name for globalization and it is too subjective to judge the extent of increase. So we exclude the globalization as the reason for corporate name changes.

Yang et al.(2009) report that managers of loss-reporting firms may take actions to accelerate the collection of receivables, and delay the purchases of inventory and payment of payables so those actions will result in the decrease of accruals. Regarding our investigation, in 260 KOSDAQ firms changing largest stockholders, 52 percentages of largest stockholders change firms have same executives with largest stockholders. DeAngelo(1988) find that the executives change firms intend to manage earnings lower to maximize next earnings when they change executives. According to previous research, we expect corporate name change of largest stockholders change firms and cosmetic change firms would have negative discretionary accruals. Therefore we set our second hypothesis to investigate the difference among the reasons for corporate name changes.

H2: There are differences of discretionary accruals among the reasons for corporate name changes.

3. Sample Selection and Research Methods

3. 1. Sample

We select our sample firms listed on Korean Securities Dealers Automated Quotations(KOSDAQ) and who change the corporate name from 2004 to 2008. The financial data were retrieved electronically from KIS-VALUE database. The data of corporate name change and industry change were on on-hand processing from KIND database in Korea Exchange. And the data of the largest stockholders change and were manually collected from business report of DART and KIS-VALUE database.

We came up with a final sample of 4,499 firm-year observations and we selected 401 firm-year observations for the corporate name change firms from 566 firm-year observations who had announced the name change.

3. 2 Research Methods

The purpose of our study is twofold: (1) descriptively analyze the trend and pattern of corporate name change and (2) empirically examine whether corporate name change associated with discretional accruals.

We first descriptively examine the current trend of corporate name change; how many firms change corporate names, how they have changed, why they change and who change names.

Second we examine empirically whether name change firms are associated with discretionary accruals. And we divide the reasons for corporate name changes into cosmetic change, industry change and largest stockholders change to focus on why they change corporate names. We examine whether there are differences among the reasons.

3. 2. 1. Estimation of Discretionary Accruals

Estimating discretionary accruals affects the success of earnings management tests. Therefore, the development of a well-fitting model is very important for this part

of research. In this research we use discretionary accruals as the proxy of earning management and we use 3 models to minimize errors from the model setting. First we use the modified Jones model (Dechow et al. 1995). Prior research documents that the modified Jones model is generally effective. Our first model is described as follows:

$$TA/BTA = b_0 + b_1(\Delta REV_i - \Delta REC_i)/BTA_i + b_2 PPE_i/BTA_i + e_i \qquad (1\text{-}1)$$

Here, TA (total accruals) = NI (net income) – CFO (cash from operations); REV = net sales revenue; REC = trade receivables; PPE = property, plant, and equipment; BTA = beginning total assets; Δ = change operator

The discretionary accruals are obtained by subtracting fitted values of accruals that is, non-discretionary accruals, from the total accruals as follows:

$$DAi = TAi/BTAi - [b0 + b1(\Delta REVi - \Delta REC i)/BTAi + b2 PPEi/BTAi] + e_i \qquad (1\text{-}2)$$

Yoon and Miller (2002) document that the modified Jones model does not fit well, particularly for Korean firms. Kothari et. al (2005) suggest that it is better to give an additional independent variable to control firms' performance in the modified Jones model when estimating discretionary accruals. Yoon and Miller (2002) find that cash from operations is the major determinant of accruals. So we include cash from operations as an additional independent variable as a control variable of performance. Our second model is described as follows:

$$TA/BTA = b_0 + b_1(\Delta REV_i - \Delta REC_i)/BTA_i + b_2 PPE_i/BTA_i + b_3 CFO_i/BTA + e_i \qquad (2)$$

The way to have the discretionary accruals and variables are same with model (1-2). Lastly Kothari et al. (2005) suggest that discretionary accrual models may be mis-specified when applied to firms with extreme past performance, proposing that a matching procedure based on performance(ROA) is more appropriate for these firms. Return on assets(ROA) is net income deflated by total assets. Consistent with

Kothari et al. (2005), we implement the 'performance-matched' discretionary accrual model.

Our third model is described as follows:

$$TA/BTA = b_0 + b_1(\Delta REV_i - \Delta REC_i)/BTA_i + b_2 PPE_i/BTA_i + b_3 ROA_i + e_i \qquad (3)$$

The way to have the discretionary accruals and variables are same with model (1-2).

3. 2. 2. Regression models

First we examine whether corporate name changes have an effect on earnings management. NC is the main variable in our model and we add control variables, we regress DA1 (2, 3) on NC and controlling for CFO, LEV, SIZE, GRW.

$$DA1 \ (DA2, DA3)_{it} = b_0 + b_1 NC + b_2 CFO_{it} + b_3 LEV_{it} + b_4 SIZE_{it} + B_5 GROW_{it} + e_{it} \qquad (4)$$

Next we regress of DA 1(2, 3) on LC, IC, OC and controlling for CFO, LEV, SIZE, GRW to investigate whether there are differences among the reasons for corporate name changes. LC is a dummy variable which has a value 1 when a firm report current loss and IC is a dummy which has a value 1 when a firm change industry from consolidation or change the primary products. OC is a dummy which has a value 1 when largest stockholders are changed for corporate name change firms.

$$DA1 \ (DA2, DA3)_{it} = b_0 + b_1 LC + b_2 IC + b_3 OC + b_4 CFO_{it} + b_5 LEV_{it} + b_6 SIZE_{it} + B_7 GROW_{it} + e_{it}$$

$$(5)$$

Model 6 is for investigating the effect of interaction of multiple factors on discretionary accruals. We add 4 interaction variables in model 5. LCOC is an interaction dummy for
name change from loss-reporting and largest stockholders change. LCIC is an interaction
dummy for name change from loss-reporting and industry change. ICOC is an interaction

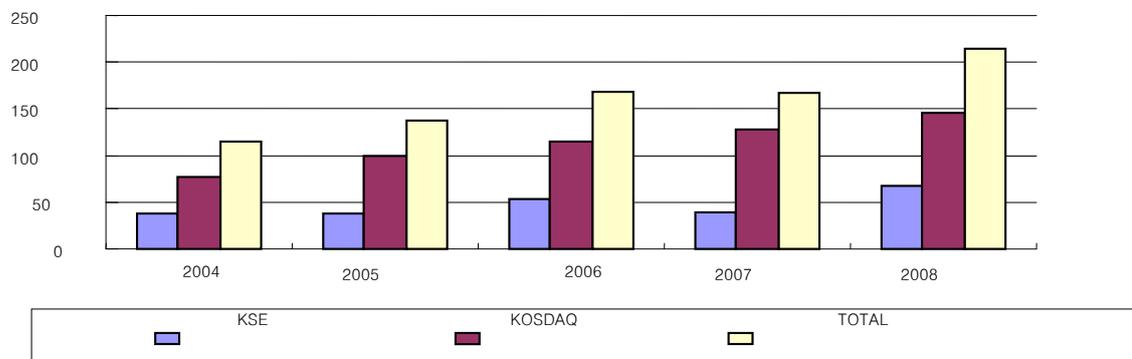
dummy for name change from largest stockholders change and industry change.
LCICOC
is interaction dummy from loss-reporting and largest stockholders change and
industry
change. Other control variables are same with model 4.

$$DA1\ (DA2, DA3)_{it} = b_o + b_1LC + b_2IC + b_3OC + b_4LCIC + b_5LCOC + b_6ICOC + b_7LCICOC$$
$$+ b_8CFO_{it} + b_9LEV_{it} + b_{10}SIZE_{it} + B_{11}GROW_{it} + e_{it} \qquad (6)$$

3. The Trend of Corporate Name Change

In this section, we briefly describe the corporate name changes in Korea in terms
of disclosure frequency, industry dispersion, the reasons for change, the pattern of
changed name. And we compare financial features with non-changing firms and
changing firms.

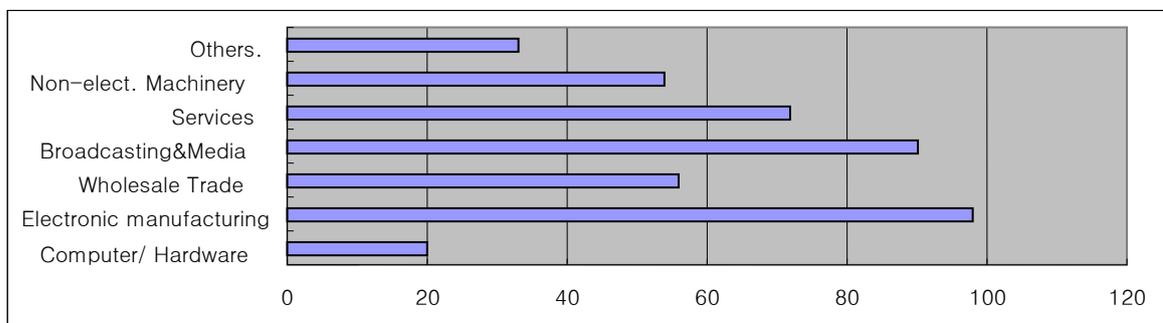
3. 1. The frequency of corporate name change

According to KIND of Korea Exchange, 131 KOSDAQ firms and 53 KSE firms
have changed their name in 2008 and they were 110 firms of KOSDAQ and 40 firms
of KSE in 2007. Figure 1 report the number of corporate name change firms from
2003 to 2008. We find that they are steadily increased, especially in the KOSDAQ
market.


[Figure 1] Frequency of corporate name change

From 2004 to 2008, there are 24 firms changing their corporate names twice in a year and 91 firms have changed their name twice for 5 years. Twenty four KOSDAQ firms have changed their names twice in a year and three firms have changed their names up to five times over the period of 2004 to 2008. So we examine the features of corporate name change based on KOSDAQ firms.

Figure 2 reports industry dispersion of corporate name change firms from 2004 to 2008.

98 Electronic·computer Manufacturing companies changed their names and 90 Broadcast and media companies and 70 service companies changed their names. It means corporate name changes happen in all over the industry, not in some industry.


[Figure 2] Industry dispersion of corporate name changes

3. 2 The Reason for Corporate name changes

According to the previous study, the reasons for corporate name change could be due to show expanded product offerings and strategic direction, to reflect company diversification and expansion, to provide a more universally representative name, and to reflect new identity following a change in ownership.

Based on previous study we partitioned the reasons for corporate name changes into 6 cases from 2004 to 2008. The largest stockholders change, the foreign ownership and export proportion data were retrieved electronically from KIS-VAUE database and the data about primary product change, consolidation and diversification during the study period were manually collected from KIND of Korea Exchange.

Table 1 report the partition of reasons for corporate name change firms who were able to figure out.

<Table 1> Reasons for corporate name changes

Reasons for corporate name changes	Numbers	Percent(%)
Change in primary products two consecutive years	18	4.6%
Industry change from spin-offs	22	5.5%
Industry change from consolidations	28	7%
Increase in foreign ownership	20	5%
Increase in export proportion	44	11.2%
Change in largest stockholders	261	66.4%
SAMPLE(2004~2008)	393	100%

We find that the 60% of corporate name change firms have changed largest stockholders at the same year. And firms who announced the reason for change to industry change from consolidation or diversification were 50 firms and 18 firms announced the reason for change to the change of the primary products. We investigate the foreign ownership and the export proportion but we find that most of the ownership and the proportion of corporate name change firms were rather decreased after changing.

We partitioned the pattern of corporate name changes in table 2. Almost 90% firms changed corporate name to English name from Korean name or to another English name from English name and only 13 firms changed to Korean name from Korean or English name.

<Table 2> Pattern of corporate name changes

Pattern of corporate name changes	Numbers	Percent(%)
from Korean/English name To Korean name	13	2
Add "holdings" for change to a holding company	12	2
Industry change	23	5
From Korean/English name To English name	462	90
SAMPLE(2004~2008)	511(Firms)	100%

According to press report, investors feel that English corporate name firms are like small, unfaithful and they generally have a negative image to English name using firms.

3. 3. Characteristics of corporate name change firms

We examine the other disclosure of corporate name changes firms to find the features of them from 2004 to 2008. According to press report, investment experts warn to invest the firms who change corporate name in the KOSDAQ because there

are so many firms changing their names to disguise negative image as stock price handling, embezzlements of management in KOSDAQ.

We find that almost 30% of corporate name changes firms are administrative issues in the KOSDAQ market. We also find that there are 140 firms who announced the embezzlements or misappropriation of management from 2004 to 2008 and 64 firms changed their name after the announcement.

We performed mean difference test to investigate the characteristics of firms who change corporate name using financial statements.

We report the result of comparison between corporate name change firms and non-changing firms in table 3. We run parallel Mann-Whitney test to minimize the problem of rare elimination of odds.

[Table 3 about here]

Table 3 shows that average leverage ratio is higher for corporate name change firms than for the control firms and there is significant difference between them. We find that there is significantly big difference between two groups in current net income and operating income. And corporate name change firms have lower cash from operations(CFO) than control firms and the difference between two groups are significantly big.

In conclusion, we find that corporate name change firms generally report bad performance comparing non-changing firms and many corporate name change firms announce the embezzlements or misappropriation of management. Also there are many corporate name change firms of administration from KOSDAQ market. And there are general changes as industry change or largest stockholders change in the corporate name change firms.

4. Empirical results

4. 1 Descriptive statistics and Variables correlation

Table 4 presents the mean, lower quartile, median, and upper quartile, standard deviation of the dependent and independent variables used in the study. Average 9 percent of KOSDAQ firms changed their name and 73 percent of them report current losses. 61 percent and 13 percent of them change the largest stockholders and industry respectively, we show that in Panel 1. Cash from operations(CFO), operating income(OP) and return in assets(ROA) of corporate name change firms is lower than total firms, it means that firms who report bad

performance tend to change their name. And the leverage ratio of corporate name change firms is higher and the size of corporate name change firms is smaller than Panel 2, so we find that the smaller firms more change their name.

[Table 4 about here]

The standard deviation of operating income and return on assets is big so that we try to minimize the eliminations of observations to represent the features of corporate name change firms. Instead we run parrel Mann-Whitney test for non-parametric statistics.

Table 5 shows the correlation coefficients between the pairs of the variables of interest for the sample in Panel 1 (corporate name change firms) and Panel 2(total firms).

[Table 5 about here]

The result of correlation analysis for both Panel 1 and Panel 2 indicates that corporate name change firm is significantly negatively correlated with discretionary accruals. It also shows that corporate name change by loss-reporting firms is significantly negatively correlated with discretionary accruals. And corporate name by largest stockholders change firms is significantly negatively correlated with discretionary accruals in panel 1. We find that cash from operations(CFO) and total accruals(TA) have a significant negative relationship and Leverage ratios have a significant negative relationship with both TA and DA.

However, the growth rate of sales and the size of firms do not exhibit significant relationship with accruals.

4. 2 Regression Analysis

The regression results for hypothesis 1 are reported in table 6.

[Table 6 about here]

The results are reported for regression DA1 (2, 3) on NC and controlling for CFO, LEV, SIZE, GRW. We do not control CFO in model 2 because we already control it during drawing model 2. For all model, the coefficients on NC are negative and significant at the .01 level.

We expect that corporate name change firms will lower their earnings because most of them have high debt-ratio or are administrative issues in the KOSDAQ market, so they can't manage earnings upward. We find that corporate name change firms have

negative discretionary accrual and the result is consistent with our expectation. All of the control variables exhibit coefficients consistent with the previous study and all variables are significant. Firms with higher debt ratio change corporate name more. Next we investigate whether there are differences of discretional accruals depending on the reason of corporate name change.

Table 7 shows the result of regression of DA 1(2, 3) on LC, IC, OC and controlling for CFO, LEV, SIZE, GRW. LC is a dummy variable which has a value 1 when a firm reports current loss and IC is a dummy which has a value 1 when a firm change industry through consolidation or change the primary products. OC is a dummy which has a value 1 when the largest stockholders are changed for corporate name change firms.

[Table 7 about here]

We expect there is difference among the corporate name changes. Yang et al.(2009) report that managers of loss-reporting firms may take actions to accelerate the collection of receivables, and delay the purchases of inventory and payment of payables. and those actions will result in the decrease of accruals. Our findings are consistent with the previous study. Corporate name change by loss-reporting firms have significantly negative discretionary accruals in all models, on the contrary the corporate name change of industry change firms and largest stockholders change firms have no significant relationship with discretionary accruals.

Therefore, the result supports hypothesis 2 that there are statistically significant differences among the reasons for corporate name changes.

Corporate name have changed by the interaction of multiple factors, by not just one factor. For example, corporate name change could be happened that the largest stockholders have changed by disposition of shares or the management right abundantly due to current bad performance. Largest stockholders could be changed following the industry consolidation or continued corporate restructuring. So we investigate the effect the interaction of multiple factors on discretionary accruals when corporate name change reasons are interplayed and table 8 reports that the result of regression.

 [Table 8 about here]

We find that corporate name change by loss-reporting firms have significantly negative discretionary accruals in all models and corporate name change of largest stockholders change firms have significantly positive discretional accruals in model 1

and 3. And corporate name change by loss-reporting and largest stockholders change firms have significantly negative relationship with discretionary accruals. It means the relationship between corporate name change by loss-reporting firms and discretionary accruals is strongest among other purpose.

Ⅴ. Conclusion

Corporate name is supposed to serve as a signal to convey information about a firm's major business or product lines. Investors will be better served as long as corporate names can be associated with major businesses or product lines. According to our investigation, there is a big increase in corporate name changes by loss-reporting firms even though it is accompanied by non-trivial costs such as consulting fees and corporate identity costs.

In this paper, we focus the purpose of the management who change their name, different from the prior study. We investigate the background to corporate name changes of Korean listed companies in the years of 2004 to 2008. We first descriptively examine the current trend of corporate name change; how many firms change corporate names, how they have changed, why they change and who change names. Second we examine empirically whether name change firms are associated with discretional accruals. We further divide the reason of corporate name change into cosmetic change to hide negative earning, industry change or consolidation and change of the largest stockholders to examine whether there are differences among the name change reasons.

We find that corporate name change firms generally report bad performance comparing non-changing firms and many corporate name change firms announce the embezzlements or misappropriation of management. Also there are many corporate name change firms of administration from KOSDAQ market. And there are general changes as industry change or largest stockholders change in the corporate name change firms. We find that name change firms have negative discretional accrual and especially name change firms with loss-reporting are significantly negatively associated with discretional accruals. This result means that there is difference among the purposes of corporate name change. And we also investigate the effect the interplay of multiple factors on discretional accruals when corporate name change purpose is interplayed, therefore we find that corporate name change of largest stockholders change with loss-reporting firms are significantly negatively

related with discretional accrual. It means that the relationship between corporate name change with loss-reporting and discretional accruals is strongest among other purposes. This result calls the validity of the corporate name change by loss-reporting firms in question.

Our study adds to the literature in the sense that it is the first attempt to examine the characteristics of firms changing their names and to investigate the impact of corporate name changes on discretionary accruals.

THE EFFECT OF EARNINGS MANAGEMENT THROUGH REAL ACTIVITIES ON FUTURE OPERATING PERFORMANCE (EMPIRICAL EVIDENCE FROM MANUFACTURING FIRMS LISTED IN INDONESIA STOCK EXCHANGE)

Rizqa Liaviani Afif , University of Indonesia
Sylvia Veronica Siregar, University of Indonesia

ABSTRACT

This research aims to examine whether firms engage in real activities manipulation through selling, general, and administrative expense, production cost, and gain on asset sales and to examine the negative impact of real activities manipulation through these three indicators on future operating performance. Samples used in this research are 116 firms. Research model used is based on Gunny (2005) model. Statistic methods employed are one sample t-test and multiple linear regressions.

The results show that manufacturing public firms in Indonesia engage in real activities manipulation through the three indicators. Moreover, this research finds that real activities manipulation through production cost has significantly negative effect on future operating performance by cash flow return on asset proxy and cannot be proved by operating income return on asset proxy. Moreover, real activities manipulation through gain on asset sales found has significantly positive effect on operating performance in short-term but insignificantly positive impact on operating performance in the long-term. However, this research does not find that real activities manipulation through selling, general, and administrative expense has significantly negative effect on future operating performance.

Keywords :   real activities manipulation, selling, general, and administrative expense, production cost, gain on asset sales, future operating performance

1. Introduction

Financial statements are prepared using accrual basis of accounting. Accrual accounting is superior compared to cash basis because of the "matching principle" (allows revenues to be matched with corresponding expenses that are incurred in the same period, without regard on the timing of cash flows). But the use of accrual basis also provide management the flexibility to choose accounting methods. When management is given that flexibility, there is a possibility that they will engage in earnings management activity (Scott, 2009). According to Gunny (2005), earnings management can be classified into three catagories: fraud, accrual manipulation, and real earnings management or real activities manipulation. Real activities manipulation can be done by 1) reducing selling, general, and administrative

expense, 2) increasing production cost, 3) gain on asset sales (Gunny, 2005; Roychowdhury, 2006).

Oktorina (2008) finds that market performance of firms engaging in manipulation through operating cash flows is higher than firms not engaging in manipulation. Graham, Harvey, and Rajgopal (2005) suggest that in doing real activities manipulation, management tends to ignore future cash flows to achieve target earnings in this period. Cash flows is often used as a measure of operating performance that shows asset capabilities in generating operating income (Pradhono and Christiawan, 2004). These indicates that real activities manipulation will effect future operating performance negatively. Gunny (2005) also finds that real activities manipulation has economically significant negative impact on future operating performance.

Empirical research concerning real activities manipulation in Indonesia is still rare. This paper aims to examine whether firms engage in real activities manipulation through selling, general, and administrative expense, production cost, and gain on asset sales and to examine the negative impact of real activities manipulation through these three indicators on future operating performance.

This paper contributes to the literature on earnings management in several ways. First, the evidence in this paper suggests that real activities manipulation through gain on asset sales has significantly positive impact on operating performance in short-term and has insignificantly positive impact on operating performance in long-term, thus, providing the evidence that in doing real activities manipulation, management is not always ignoring future operating performance. Second, we find no evidence that real activities manipulation through selling, general, and administrative expense has significantly negative impact on future operating performance. This finding maybe due to the presumation that manipulation is done repeatedly on the following years.

2. Literature Review

2.1 Earnings Management

According to Scott (2009), earnings management is "*the choice by a manager of accounting policies, or actions affecting earnings, so as to*

achieve some specific reported earnings objectives". Gunny (2005) asserts that earnings management can be classified into three categories, such as fraudulent accounting, accruals management, and real earnings management. Fraudulent accounting involves accounting choices that violate GAAP. Accruals management involves within-GAAP choices that try to "obscure" or "mask" true economic performance (Dechow and Skinner, 2000; in Gunny, 2005). Real earnings management occurs when managers undertake actions that deviate from the first best practice to increase reported earnings (Gunny, 2005).

Fraudulent accounting and accruals management are not accomplished by changing the underlying economic activities of the firm but through the choice of accounting methods used to represent those underlying activities. In contrast, real earnings management involves changing the firm's underlying operations in an effort to boost current period earnings. Examples of real earnings management are cutting prices toward the end of the year in an effort to accelerate sales from the next fiscal year into the current year, delaying desirable investment, and selling fixed assets to affect gains and losses.

2.2   Real Activities Manipulation

Roychowdhury (2006) defines real activities manipulation as departures from normal operational practices, motivated by managers' desire to mislead at least some stakeholders into believing certain financial reporting goals have been met in the normal course of operations. These departures do not necessarily contribute to firm value even though they enable managers to meet reporting goals. Consistent to the definition by Roychowdhury (2006), Graham, Harvey, dan Rajgopal (2005) suggest that manager will manipulate their real activities to accomplish earnings target, eventhough these will decrease firm value in the long run.

Graham, Harvey, dan Rajgopal's (2005) survey finds that (a) financial executives attach a high importance to meeting earnings targets such as zero earnings, previous period's earnings, and analyst forecasts, and (b) they are willing to manipulate real activities to meet these targets, even though the manipulation potentially reduces firm value.

Real activities manipulation can reduce firm value because actions taken in the current period to increase earnings can have a negative effect on cash flows in future periods. For example, aggressive price discounts to increase sales volumes and meet some short-term earnings target can lead customers to expect such discounts in future periods as well. This can imply lower margins on future sales. Overproduction generates excess inventories that have to be sold in subsequent periods and imposes greater inventory holding costs on the company.

2.3 Real Earnings Management Technique

According to Roychowdhury (2006), there are three ways for management in doing real earnings manipulation: sales manipulation through increased price discounts or more lenient credit term, reduction of discretionary expenditures, and overproduction. Gunny (2005) adds one more way which allows manager to manipulate, that is timing the sale of fixed assets to report gains so that recognition of gain on asset sales can increase the reported earnings amount.

Production costs are defined as the sum of COGS and change in inventory during the period. By using production costs variable instead of COGS, as one of real activities manipulation indicator, eliminates the possibilities of accrual manipulation in reporting lower COGS by delaying write-offs of obsolete inventory. This accrual manipulation effect does not impact production costs, so that production costs primarily reflect the effects of real activities. Moreover, the LIFO/FIFO cost flow assumption affects reported COGS, but not production costs, due to offsetting effects on COGS and inventory change.

2.3.1 Sales Manipulation

Roychowdhury (2006) defines sales manipulation as managers' attempts to temporarily increase sales during the year by offering price discounts or more lenient credit terms. Jackson and Wilcox (2000), in Xu, Taylor, dan Dugan (2007) finds that manager grant sales price reductions in the fourth quarter to avoid reporting losses and decreases in earnings and sales. The increased sales volumes as a result of the discounts causes higher cash

inflows, but the cash inflow per sale, net of discounts, from these additional sales is lower as margins decline. The lower margins due to the price discounts causes production costs relative to sales to be abnormally high.

Another way to boost sales volumes temporarily to increase earnings is to offer more lenient credit terms (*zero-percent financing*) at the end of fiscal year. These are essentially price discounts and lead to lower cash inflow over the life of the sales, as long as suppliers to the firm do not offer matching discounts on firm inputs. These sales management activities lead to lower current-period CFO and higher production costs than what is normal given the sales level.

2.3.2 Discretionary Expenditure Reductions

Discretionary expenditures are expenses for firms as they incurred (*period costs*) which management has control in deciding the amount of reported expenses, such as R&D, advertising, and maintenance (Roychowdhury, 2006). By its control, management can reduce reported expenses, and increase earnings. If managers reduce discretionary expenditures to meet earnings targets, they should exhibit unusually low discretionary expenses. In effect, lowers cash outflows, so that has a positive effect on abnormal operating cash flows in the current period, possibly at the risk of lower cash flows in the future.

2.3.3 Overproduction

According to Roychowdhury (2006), in favor of manage earnings upward, managers of manufacturing firms can produce more goods than necessary to meet expected demand. By higher production levels, fixed overhead costs are spread over a larger number of units, lowering fixed costs per unit. As long as the reduction in fixed costs per unit is not offset by any increase in marginal cost per unit, total cost per unit declines. This implies that reported COGS is lower, and the firm reports better operating margins. Nevertheless, the firm incurs production and holding costs on the over-produced items that are not recovered in the same period through sales. As a result, cash flows from operations are lower than normal given sales levels. Ceteris paribus, the

incremental marginal costs incurred in producing the additional inventories result in higher annual production costs relative to sales.

2.3.4 Timing the Assets Sales

According to Gunny (2005), the timing of asset sales is a manager's choice, and since a gain is reported on the income statement at the time of the sale (the difference between the net book value and the current market value), the timing of asset sales could be used as a way to manage reported earnings. Bartov (1993), in Gunny (2005) provides evidence consistent with managers selling fixed assets in order to avoid negative earnings growth and debt covenant violations. Herrmann, Inoue and Thomas (2003), in Gunny (2005) investigate Japanese managers' use of income from the sale of assets to manage earnings. They find that firms increase (decrease) earnings through the sale of fixed assets and marketable securities when current operating income falls below (above) management's forecast of operating income.

2.4 Future Operating Performance

Net income are affected by operating decision and how a firm is financed. In analyzing operating performance of a firm, any effect of financing activities to earnings should be isolated. Financing activities, like dividend, interest income, and realized/unrealized gains should be separated from operating activities because financing performance can distort the operating performance (Wild et al, 2003; in Hasyim, 2006). Operating income is calculated before financing expense, such as interest expense, is deducted. So that, operating income is a more suitable operating performance proxy than earnings. Furthermore, according to Pradhono (2004), cash flows are more valuable to assure firm performance in the future. Cash flows shows the results of operations which the fund has been received by the firm and also, charged by the cash expenses and the expenses has been paid by the firm (Pradhono, 2004). Therefore, both operating income and cash flows are the best proxy to measure operating performance.

2.5 Prior Research

One of the prior research which examine real activities manipulation is research from Roychowdhury (2006) which examine the impact of earnings management through real activities manipulation on operating cash flows. Firms that reports low earnings is categorized as suspect firms, that is firms inclined of doing earnings management, because firms with low earnings tend to do earnings management by increasing earnings. The model used by Roychowdhury (2006) is Dechow, Kothari, and Watts (1998) model to estimate normal operating cash flows or expected operating cash flows. After estimating the normal operating cash flows, the deviation between actual and normal operating cash flows is calculated which be called abnormal operating cash flows. Roychowhury (2006) finds that real activities manipulation has impact on operating cash flows, that is firms doing real activities manipulation report abnormal operating cash flows compared to firms which is not detected of doing real activities manipulation.

Prior research which examine real activities manipulation and future operating performance is Gunny's (2005) research. Gunny (2005) investigates the consequences of real activities manipulation on operating performance in future period. The result indicates that firms doing real activities manipulation will find earnings and operating cash flows decreasing significantly in future period. In her research, Gunny (2005) uses performance-matching approach which the performance of each firms inclined of doing real activities manipulation compared to firms inclined of not doing real activities manipulation (compared firms) in the same year.

Research in Indonesia that examine real activities manipulation in relation to future performance were done by Rahman (2007) and Oktorina (2008). Rahman (2007) identifies real activities manipulation and accrual manipulation and also its impact on market and operating performance of IPO firms. The result shows that the motivation of earnings management when IPO is using discretionary accrual proxy, but not using real activities manipulation proxy. Oktorina (2008) identifies the firm's tendency to execute real activities manipulation through cash flow and its impact to market performance. The result shows that firm tend to execute real activities manipulation through operating cash flowbut not through investing and financing cash flow. Moreover, the impact of real activities manipulation on

market performance shows that firms are more likely executing real activities manipulation have higher market performance than their counterparts.

2.6 Hypotheses Development

Based on literature review, known that the four ways of how management doing real activities manipulation, that is by; manipulating sales through price discount and more lenient credit terms, reducing discretionary expense, overproduction, and timing of asset sales, will affect the amount of selling, general, and administrative expense, production cost, and gain on asset sales reported. This indicates that these three indicators could be used to examine whether firms doing real activities manipulation or not. The examination is done by using the abnormal value of three manipulation indicators. The abnormal value is the difference between normal value and actual value. Gunny (2005) and Roychowdhury (2006) focus on earnings management pattern which increases the amount of earnings reported, whereas our paper focus on the absolute value of real activities manipulation.

Because the real activities manipulation in recent period to increase earnings causing negative impact on future cash flows, this manipulation is inclined could decrease the firm's future operating performance. Referring to the result of Gunny's (2005) research, the abnormal value of selling, general, and administrative expense, production cost, and gain on asset sales will have a significant negative relationship with future operating performance which the abnormal value of selling, general, and administrative expense, production cost, and gain on asset sales are real activities manipulation proxies. However, Hillier, McColgan, dan Werema (2005) finds that the asset sales activities directs on firm's future operating performance increasing significantly.

In this paper, the dependent variable is future operating performance and the independent variables are; (1) real activities manipulation through selling, general, and administrative expense, (2) real activities manipulation through production cost, and (3) real activities manipulation through gain on asset sales.

Roychowdhury (2006) finds that firms inclined of doing real activities manipulation reports low abnormal discretionary expense. Beside that, firms

inclined of doing manipulation through excessive price discounts have high abnormal production cost. Also, firms inclined of doing manipulation through gain on asset sales have high abnormal gain on asset sales.

Hypothese 1a. Firms are engaging in real activities manipulation through selling, general, and administrative expense.

Hypothese 1b. Firms are engaging in real activities manipulation through production cost.

Hypothese 1c. Firms are engaging in real activities manipulation through gain on asset sales.

Firms tend to ignore future cash flows on firms doing real activities manipulation (Graham, Harvey, dan Rajgopal, 2005) to increase current earnings, however the future operating performance will decrease (Gunny, 2005). We use two operating performance measure: OIROA and CFROA.

Hypothese 2a. Real activities manipulation through selling, general, and administrative expense has a significant negative relationship with operating performance (OIROA) in one, two, and three years later.

Hypothese 2b. Real activities manipulation through production cost has a significant negative relationship with operating performance (OIROA) in one, two, and three years later.

Hypothese 2c. Real activities manipulation through gain on asset sales has a significant negative relationship with operating performance (OIROA) in one, two, and three years later.

Hypothese 2d. Real activities manipulation through selling, general, and administrative expense has a significant negative relationship with operating performance (CFROA) in one, two, and three years later.

Hypothese 2e. Real activities manipulation through production cost has a significant negative relationship with operating performance (CFROA) in one, two, and three years later.

Hypothese 2f. Real activities manipulation through gain on asset sales has a significant negative relationship with operating performance (CFROA) in one, two, and three years later.

3.   Research Methodology

3.1   Research Model

The focus in this paper is on the existence of real activities manipulation, not the sign (increasing or decreasing earnings). That is why we use absolute value of each real activities manipulation.

H_{1a} : $\mu_{ABNSGA} \neq 0$

H_{1b} : $\mu_{ABNProdCost} \neq 0$

H_{1c} : $\mu_{ABNGAIN} \neq 0$

To test our second hypotheses, we use following research model:

$$FOP_{i,t+y} = \beta_0 + \beta_1 ABNSGA_{i,t} + \beta_2 ABNProdCost_{i,t} + \beta_3 ABNGAIN_{i,t} + \beta_4 LNASSET_{i,t} + \beta_5 BTM_{i,t} + \beta_6 OIROA_{i,t} + \beta_7 D03_i + \beta_8 D04_i + \varepsilon$$

Where :

$FOP_{,t+1}$ = future operating performance, which measured using : 1) $OIROA_{i,t+y}$ and 2) $CFROA_{i,t+y}$

$ABNSGA_{i,t}$ = log abnormal value of selling, general, and administrative expense

$ABNProdCost_{i,t}$ = abnormal value of production cost

$ABNGAIN_{i,t}$ = abnormal value of gain on asset sales

$LNASSET_{i,t}$ = natural logarithm of total asset

$BTM_{i,t}$ = growth opportunity (equity book value/equity market value)

$OIROA_{i,t}$ = rate of operating income return before interest and tax toward assets

$D03_i$ = 1 if the observation year is 2003 and 0 if otherwise

$D04_i$ = 1 if the observation year is 2004 and 0 if otherwise

Control Variables

▪ LNASSET is used as a control variable because it is convinced that the firm's size has a relationship with future operating performance. In big firms, as having high total assets, they are able to generate higher operating income compared to small firms which having lower total assets.

▪ BTM is considered as a control variable because this variable is inclined of having relationship with future operating performance. According to McNichols (2000), in Siregar (2005), firms with high growth rate will be more correlated to firm's performance. Low BTM ratio shows a high growth opportunity for the firm. An opportunity to grow accomodates the increasing

of future operating performance. So that, the lower BTM ratio, the higher the future operating performance.

▪ OIROA variable is considered as a control variable because it is convinced that rate of operating income return on firm's total asset in year t affects future operating performance. The better operating performance in this period, the better operating performance in next period.

▪ D03 and D04 variables are dummy variables of observation period to account for the adjusted mean difference of dependent variables between years in research period.

3.2 Variable Definition

3.2.1 Dependent Variable

The future operating performance dependent variable is measured by *Operating Income Return on Assets* (OIROA) ratio and *Cash Flows Return on Assets* (CFROA) ratio.

$$OIROA_{i,t} = \frac{Operating\ Income_{i,t}}{TA_{i,t}}$$

Where:

Operating Income$_{i,t}$: operating income before interest and yearly tax on i firms t year

$$CFROA_{i,t} = \frac{Operating\ Cash\ Flows_{i,t}}{TA_{i,t}}$$

Where:

Operating Cash Flows$_{i,t}$: cash flows from operating activities on i firms t year

3.2.2 Independent Variables

a. Real activities manipulation through selling, general, and administrative expense

This manipulation is measured by log abnormal value of selling, general, and administrative expense (ABNSGA) which known by regressing the Gunny's (2005) estimation model which referring to Anderson et al.'s

(2004) model. Consistent to Anderson et al. (2004), the model uses variable log spesifications and deflating all variables with SGA in a year before to control heteroskedasticity and *scaling effect*. The estimation model is as mention below:

$$\log\left(\frac{SGA_{i,t}}{SGA_{i,t-1}}\right) = \alpha_0 + \alpha_1 \log\left(\frac{S_{i,t}}{S_{i,t-1}}\right) + \alpha_2 \log\left(\frac{S_{i,t}}{S_{i,t-1}}\right) \times Sdown$$

$$+ \alpha_3 \log\left(\frac{S_{i,t-1}}{S_{i,t-2}}\right) + \alpha_4 \log\left(\frac{S_{i,t-1}}{S_{i,t-2}}\right) \times Sdown + \varepsilon$$

Where :

$SGA_{i,t}$ = selling, general, and administrative expense plus advertising or promotion expense on i firms t year

$S_{i,t}$ = net sales

$Sdown$ = dummy variable will be equal to 1 if net sales in t period is decreasing compared to net sales in (t-1) period and 0 if otherwise

b. Real activities manipulation through production cost

This manipulation is measured by abnormal value of production cost (ABNProdCost) (Dechow et al., 1998; Roychowdhury, 2006).

$$\frac{ProdCost_{i,t}}{TA_{i,t-1}} = \alpha_0 + \alpha_1 \frac{1}{TA_{i,t-1}} + \alpha_2 \frac{S_{i,t}}{TA_{i,t-1}} + \alpha_3 \frac{\Delta S_{i,t}}{TA_{i,t-1}}$$

$$+ \alpha_4 \frac{\Delta S_{i,t-1}}{TA_{i,t-1}} + \varepsilon$$

Where :

$ProdCost_{i,t}$ = the total of production cost (COGS +ΔINV) on i firm t year

$\Delta S_{i,t}$ = the difference in net sales

c. Real activities manipulation through gain on asset sales

This manipulation is measured by abnormal value of gain on asset sales (ABNGAIN) which known by regressing the Gunny's (2005) estimation model as below.

$$\frac{GAIN_{i,t}}{MV_{i,t-1}} = \alpha_0 + \alpha_1 \frac{AssetSale}{MV_{i,t-1}} + \alpha_2 \frac{InvSale_{i,t}}{MV_{i,t-1}}$$

$$+ \quad \alpha_3 \log(S_{i,t}) + \alpha_4 \, SGrowth + \varepsilon$$

Where :

$GAIN_{i,t}$ = gain on asset sales on i firm t year

AssetSale = long term asset sales value

SGrowth = net sales growth of the preceding period (%)

3.2.3 Control Variables

Control variables used in this research: (1) Size of firms (LNASSET) measured by natural logarithm of total assets at year end, (2) Growth opportunity (BTM) which measured by BTM ratio where equity book value at the year end is divided by equity book value at year end, (3) Operating performance in this period (OIROA) measured by *operating income return on assets* ratio at year end, and (4) Observation years which definited as years of 2002 – 2004 by years of 2002 as base year, D03 = 1 if the observation year is 2003 and 0 if otherwise, and $D04_i$ = 1 if the observation year is 2004 and 0 if otherwise.

3.3 Sample Selection

Samples are selected from all population of manufacturing firms listed in Indonesia Stock Exchange (ISE), with following criteria: (1) Manufacturing firms has been listed in ISE since 2000 until 2007, (2) Using Rupiahs as reporting currency in financial reports, (3) The accounting period starts from January 1 until December 31, and (4) Has complete needed data.

3.4 Data Collection Methods

Data used in this paper are secondary data, that is yearly financial reports of the firms on year 2000-2007. The yearly financial reports datas collected through observations are obtained from CD-ROM OSIRIS *database* of public firms in Indonesia which belongs to Economy and Business Data Center of Faculty of Economics University of Indonesia, Stock Market Reference Center of Indonesian Stock Exchange, and www.idx.co.id.

Moreover, last year stock price data to calculate market values are obtained from subscribe Metastock which belongs to PT Finansial Bisnis Informasi and www.yahoo.com/finance. The classifications of manufacturing firms are based on *Indonesian Capital Market Directory* (ICMD) 2007.

Table 3.1

Sample Selection Procedure

Keterangan	Jumlah
Manufacturing firms listed in ISE on 2007	142
Sample selection criterias :	
Has not been listed in ISE since 2000 until 2007	(18)
Not using Rupiahs as financial reporting currency	(6)
Year end period other than December 31	(1)
Incomplete available datas	(1)
Firms that do not fulfill the sample selection criterias	(26)
Total Research Samples	**116**

4. Analysis

4.1 Descriptive Statistics

Descriptive statistics of variables used is presented in Table 4.1. Based on Table 4.1, the average of log abnormal value of selling, general, and administrative expense (ABNSGA) is 0,0703; the average of abnormal value of production cost (ABNProdCost) is 0,1523; and the average of abnormal value of gain on asset sales (ABN GAIN) is 0,0130. This may indicate that in average public manufacturing firms in Indonesia are doing real activities manipulation through the three indicators (SGA, ProdCost, and GAIN).

In addition, sample firms, have positive OIROA and CFROA. Our samples in average consist of profitable firms. The average value of asset total (in million) of whole samples is Rp 1,864,146.22 by the maximum value of Rp 39,145,102 and minimum value of Rp 33,434. This indicates that samples varies from small firms and big firms. Moreover, sample firms have *book-to-market* ratio average for -1,1330. These indicates that in average, sample firms on year 2002-2004 do not have high growth opportunity.

Table 4.1

Descriptive Statistics

	Mean	Median	Std. Deviation	Minimum	Maximum
OIROA(t+1)	0.0682	0.0673	0.1418	-0.6737	1.2865
OIROA(t+2)	0.0705	0.0659	0.1411	-0.6737	1.2865
OIROA(t+3)	0.0732	0.0694	0.1375	-0.6620	1.2865
CFROA(t+1)	0.0705	0.0673	0.1378	-0.6315	1.2865
CFROA(t+2)	0.0556	0.0540	0.1166	-0.6315	0.4701
CFROA(t+3)	0.0532	0.0528	0.1195	-0.6315	0.4701
ABNSGA	0.0703	0.0472	0.0850	0.0000	0.6258
ABNProdCost	0.1523	0.0873	0.1745	0.0001	1.1236
ABNGAIN	0.0130	0.0085	0.0248	0.0000	0.2234
TOTALASSET	1,864,146.22	534,249.50	4,031,570.17	33,434	39,145,102
BTM	-1.1330	0.9679	13.9074	-162.9636	22.3334
OIROA	0.0591	0.0586	0.1330	-0.6786	0.5566

OIROA(t+1) and CFROA(t+1) = operating performance in one year later, OIROA(t+2) and CFROA(t+2) = operating performance on two years later, OIROA(t+3) and CFROA(t+3) = operating performance in three years later, ABNSGA = log abnormal value of selling, general, and administrative, ABNProdCost = abnormal value of production cost, ABNGAIN = abnormal value of gain on asset sales, TOTALASSET = total asset (in millions), BTM = firm's opportunity to grow, OIROA = operating performance in this period.

The value of real activities manipulation above can be identified into two patterns, which is income-increasing pattern and income-decreasing pattern. Income-increasing pattern is indicated by negative log abnormal value of selling, general, and administrative expense and positive abnormal value of production cost and gain on asset sales. If vice-versa, then income-decreasing pattern occurs. Descriptive statistics of the three real activities manipulation variables which classified based on manipulation pattern done can be seen on Table 4.2 below.

Table 4.2

Descriptive Statistics – Real Activities Manipulation Variables

	Income-increasing Pattern			Income-decreasing Pattern		
	Mean	Median	Std. Deviation	Mean	Median	Std. Deviation
ABNSGA	-0.0764	-0.0491	0.0873	0.0650	0.0424	0.0829
ABNProdCost	0.1299	0.0876	0.1274	-0.1841	-0.0872	0.2217
ABNGAIN	0.0342	0.0116	0.0515	-0.0080	-0.0085	0.0037

ABNSGA = log abnormal value of selling, general, and administrative, ABNProdCost = abnormal value of production cost, ABNGAIN = abnormal value of gain on asset sales.

Based on Table 4.2 above, the average value of ABNSGA, ABNProdCost, and ABNGAIN on income-increasing samples is relatively not very different from income-decreasing samples. These shows any variations of real activities manipulation behavior pattern, in average, which is not just income increasing, but also income decreasing. By focusing only on one earnings management pattern, it wiil reduce the power of the test as has been revealed by Roychowdhury (2006). In order to avoid that, this paper is not limited only on one direction of real activities manipulation.

4.2   Hypothesies 1 Results

Table 4.3

Hypotheses 1 Results

Variable	Mean	p-Value(2-tailed)		Explanation
ABNSGA	0.0703	0.0000	***	H1a is not rejected
ABNProdCost	0.1523	0.0000	***	H1b is not rejected
ABNGAIN	0.0130	0.0000	***	H1c is not rejected

ABNSGA = log abnormal value of selling, general, and administrative, ABNProdCost = abnormal value of production cost, ABNGAIN = abnormal value of gain on asset sales.
*** represent statistical significance at α equals to 1%

Table 4.3 shows that real activities manipulation through selling, general, and administrative expense (ABNSGA), production cost (ABNProdCost), and gain on asset sales (ABNGAIN) have averages of 0,0703; 0,1523; and 0,0130. The significance value of the three abnormal values which equals to 0,0000 indicates that that firms do engage in real activities manipulation (hypotheses 1a, 1b, dan 1c are not rejected on confidence level of 99%). Based on these explanations, can be concluded that firms are inclined of doing real activities manipulation through selling, general, and administrative expense, production cost, and gain on asset sales.

4.4 Hypotheses 2 Results

Based on Table 4.4, ABNSGA do not have significant negative impact on future operating performance year, 2 years, and 3 years ahead, therefore, hypotheses 2a and 2d are rejected. The possible explanation of this findings is real activities manipulation through selling, general, and administrative expense is done repeatedly on the following years. This will make the negative impact emerged by real activities manipulation in last year on operating performance in next year is not detected.

The negative and coefficient sign of ABNProdCost shows that the higher production cost manipulation, the lower operating performance measured using *cash flow return on assets* in 1 year, 2 years, and 3 years ahead, but it is not significant if we use *operating income return on assets* proxy. Therefore, hypothese 2b is rejected and hypothese 2e is not rejected. The possible interpretation of this is management maybe engaging in accruals earnings management practice in the later years and so this will cover the negative impact of real activities manipulation through production cost on operating income in the next years. The accrual effect due to earnings management do not affect the cash flows reporting, so that the cash flows reported in the next years reflect the significant negative impact of real activities manipulation through production cost on future operating performance. Our finding that production cost manipulation have negative impact on future *cash flow return on assets* consisten with Gunny (2005) who also finds that real activities manipulation has economically significant negative impact on future operating performance.

The average abnormal value of gain on asset sales (ABNGAIN) has positive and significant impact on operating performance in 1 year ahead, but insignificant impact on operating performance in 2 years and 3 years ahead (hypothesis 2c and 2f are rejected). The possible interpretation of this is cash inflows obtained from gain on asset sales maybe used by the firms for genuine purposes (John and Ofek, 1995 in Hillier, McColgan, and Werema, 2005) such as settling existing debt and financing working capital needs after asset sales, and hence eventually increase operating performance in one period ahead.

Firms size (LNASSET) has positive and significant impact on long-term operating performance, which is consistent with Gunny (2005) which finds that size variable influences future operating performance positively. Growth opportunity (BTM) do not has significant impact on operating performance. These might be due to BTM variable is not a good proxy of growth opportunity for firms in Indonesia. Adam dan Goyal (2007) finds that *market-to-book assets* ratio is the best variable to measure the opportunity to invest for firms, while Hutchinson (2002) uses *market-to-book assets* ratio as proxy of growth oppotunity. The observation period dummy variable (D03 and D04) on operating performance model in 1 year later is significantly positive on both operating performance proxies.

Dependent Variables: Future Operating Performance measured by *Operating Income Return on Assets* (Panel A) and Future Operating Performance measured by *Cash Flow Return on Assets* (Panel B). Independent Variables: ABNSGA = log abnormal value of selling, general, and administrative, ABNProdCost = abnormal value of production cost, ABNGAIN = abnormal value of gain on asset sales, LNASSET = natural logarithm of total asset, BTM = growh opportunities, OIROA = this period operating performance, D03 = 1 for observation year 2003 and 0 if else, D04 = 1 for observation year 2004 and 0 if else.

*** represent statistical significance at α equals to 1%.
** represent statistical significance at α equals to 5%.
* represent statistical significance at α equals to 10%.

5. Conclusion

This research finds that public manufacturing firms in Indonesia do engage in real activities manipulation through selling, general, and administrative expense, production cost, and gain on asset sales. We also finds that real activities manipulation through selling, general, and administrative expense has insignificantly negative impact on future operating performance. Real activities manipulation through production cost has significantly negative impact on future operating performance, only if we use cash flow return on asset. Also, real activities manipulation through gain on asset sales found has significantly positive impact on operating performance in short-term (one-year ahead) and has insignificantly positive impact on operating performance in two and three years later. These are consistent to Hillier, McColgan, dan Werema (2005) which asserts the raising of operating performance after asset sales are done.

There are several limitations of this paper. First, we do not consider stock return of this period variable in predicting the future operating performance. This variable controls any relationship between stock performances with future earnings, as according to Kothari and Sloan (1992) in Gunny (2005), stock price in this period can predict future earnings. Second, we only use two proxies to measure operating performance, that is *operating income return on assets* and *cash flow return on assets*. Palepu, Bernard, and Healy (2004) reveals that in analyzing operating activities of a firm, *gross profit margin, net operating profit margin*, *EBITDA margin,* and *return on assets* proxies can be used.

2.4 Capital Markets

LIFE AFTER IPO:
FINANCING AND INVESTING ACTIVITIES OF NEW PUBLIC LISTED
FIRMS IN INDONESIA

Dezie L. Warganegara, BINUS University
Josephine Nicole , Stern Stewart & Co, Singapore.

Abstract

The objective of this study is to investigate the use of IPO raised fund by new Indonesian public firms. It is found that Indonesian IPO companies utilize their IPO generated fund to finance their future investment, not to enhance their financial flexibility. In addition, instead of reducing their long term debt following the IPOs, these companies use more long term debt in the post-IPO periods. However, the IPO firms in this study rely heavier on the equity financing than debt financing to fund their investment in real assets. Further investigation reveals that there is a positive relationship between the amount of funds raised in the IPOs and the decision to increase leverage at the one year after the IPOs.

1. **Introduction**

An Initial Public Offering (IPO) is commonly perceived as one of the most important milestones in a company's life cycle. The underlying reasons of a company to go public comprise both financial and non-financial aspects. Geddes (2003) identifies that in the context of primary offering, with the intention to finance its future growth, the company can use the generated funds to increase its cash holdings, increase the spending on inventory, Property Plant and Equipment (PPE), capital expenditure, or on R&D. Otherwise, the company can use the proceeds to rebalance their leverage by repaying its long term debt and/or by enhancing its liquidity. In contrast, in the context of secondary offering, another objective is to provide exit strategy for the initial owners. This IPO allows the initial shareholders to sell a portion of

their holdings in the company and utilize the funds generated to diversify their personal portfolio and pursue new ventures at the company level.

Reflecting the importance of this going public decision of a company, there has been numerous empirical literatures focusing prominently on IPO. However, these literatures have surprisingly ignored the investigation to the actual utilization of proceeds from this IPO. As an alternative, the majority of them discuss about the under pricing, the long-run performance, and the time-clustering of IPOs (Ibbotson, Sindelar, & Ritter, 1994; Jenkinson & Ljungqvist, 2001; or Ritter, 2003). In addition, most corporate finance literatures limit themselves to describing the institutional aspects of this decision, providing only a few remarks on the investigation of the actual utilization of the generated IPO funds. As a matter of fact, this information is very useful for the investors to make optimal investment decisions because this particular information can enable them to have a better view on how the company actually utilizes their money to increase the shareholder's wealth.

Moreover, this growing significance in the decision of a company to go public can be considered as particularly high in Indonesia. As the evidence, according to the data from the Indonesia Stock Exchange (IDX), the ratio of market capitalization to the Gross Domestic Products (GDP) in Indonesia is relatively low (14.7% in 2002, 29.4% in 2005, 37% in 2006, and 53% in 2007) being compared to other Asian countries like Malaysia and Singapore, which ratios have exceeded 200%.[81] However, it can be seen that this ratio keeps increasing from year to year, which depicts the growing potential of capital markets in Indonesia that is very considerable. Accordingly, capital markets

---

[81] Source: Danareksa Research Institute, *Analisa Faktor Pencetus Voluntarily Delisting di Pasar Modal Indonesia* 2007. Retrieved December 27, 2007, from http://www.danareksa-research.com

have recently become an important source of financing for companies in Indonesia and many investors have perceived capital markets as an attractive place to put their money in. This positive signal means that capital markets can already give a contribution to the economic growth in Indonesia.

This study looks at the changes in the financial flexibility and investment following IPOs. It is found that Indonesian IPO companies utilize their IPO generated fund to finance their future investment, not to enhance their financial flexibility. In addition, instead of reducing their long term debt following the IPOs, these companies even use more long term debt in the post-IPO periods. Further investigation reveals that there is a positive relationship between the amount of funds raised in the IPOs and the decision to increase leverage at the one year after the IPOs. Finally, it is found that the IPO firms in this study rely heavier on the equity financing than debt financing to fund their investment in real assets. The results of this part of the study supports the findings of Mikkelson et al. (1997) and Kim and Weisbach (2006) that the motive for the companies to go IPO is to raise capital for investment.

The remainder of this paper is organized as follows. Section Two contains the data used in this study. Section Three reports the empirical results on the use of IPO raised funds of new public firms in Indonesia. Section Four discusses the investing activities of IPO firms after becoming public firms. Section Five documents the relationship between the amount of funds raised in the IPOs and the decision to increase leverage at the one year after the IPOs. The last section offers the final conclusions on this study.

2. Data

The initial samples in this study consist of all firms that conducted Initial Public

Offering within year 2000 to 2005 at the Indonesia Stock Exchange (IDX).

The IDX Annual Statistics publication was the source to collect the initial

sample. There were 96 firms conducted IPOs during the sample periods of

this study. To be included in the final sample, those 96 IPO firms have to meet

several requirements, as follows:

1. Not companies classified into finance industry. Thus, 28 IPO companies
   are excluded
   due to this requirement.
2. Not state-owned enterprises (SOEs). This study limits to firms that
   conducted primary
   offerings only. During the sample period of this study, Indonesian
   government sold 5 SOEs to public as part of privatization program, among
   other things, for state budget deficit relief following the 1997 Asian Financial
   Crisis.
3. Have a complete set of financial data required to estimate Working Capital
   Requirements (WCR), Gross Property, Plant, and Equipment (PPE), Net
   Liquid Balance (NLB), Long Term Debt (Leverage), and Growth
   Opportunities, and Total Assets at the 1 year before and after the IPOs. Ten
   IPO companies were further eliminated since they do not have complete
   data available to be further used in this study.

In total, there are 43 of IPO firms excluded from the final sample. This leaves

the final sample with 53 IPO companies from 8 industry sectors, as depicted

in the Table 1 below:

Table 1
IPO Companies and Industry Sectors

Industry Sectors	2000	2001	2002	2003	2004	2005	Total
Agriculture	1	0	1	0	1	0	3
Mining	0	1	3	0	0	0	4
Basic Industry and Chemicals	2	4	1	0	1	0	8
Miscellaneous Industry	1	1	1	1	1	1	6
Consumer Goods Industry	0	1	0	0	0	0	1
Property, Real Estate & Building Construction	3	3	0	0	0	0	6

Infrastructure, Utilities & Transportation	0	1	0	1	0	2	4
Trade, Services & Investment	0	10	7	0	3	1	21
Total	7	21	13	2	6	4	53

Table 1 above shows that the final samples of this study mostly consist of firms from Trade, Services, & Investment sector. This sector counts for more than 39% (21 out of 53 IPOs) of the total sample. The smallest numbers of IPOs come from the Agriculture and Consumer Goods Industry, which are only around 2% (1 out of 53 IPOs). Moreover, the final samples in this study are dominated by IPOs done in the period of 2001, which are also made up of more than 39% (21 out of 53 IPOs) of the total IPOs across the sample periods. Year 2003, however, is the period with the least number in the sample. Only around 4% (2 out of 53 IPOs) comes from year 2003.

Table 2
Descriptive Statistics

	Mean	Min.	Max.	Std. Dev.
ROA	7%	-124%	254%	39%
Leverage	1.57	0.00	69.87	9.59
Size (IDR billion)	326	10	6,474	937

ROA is calculated by dividing a company's annual net income by its total assets, in a year before IPO. Leverage is calculated by dividing a company's long term debt by its equity, in a year before IPO. Size is the value of the total assets prior to the IPO year, expressed in Indonesian Rupiah (IDR billion).

Table 2 above shows that IPO companies in this study one year before going public, on average, book for 7% in their ROA, with the maximum and minimum of 254% and -124%, respectively. PT Multistrada Arah Sarana Tbk was the company that had the highest ROA prior to its IPO in 2005. On the other hand, PT Metamedia Technologies Tbk was the company with the lowest ROA prior to its IPO in 2001. Furthermore, table 2 above also shows that the sample IPO companies have varying levels of leverage. The average

leverage of the sample IPO companies is 1.57 with the maximum and minimum of 69.87 and 0, respectively. The company that is highly levered was PT Aneka Kemasindo Utama Tbk, prior to its IPO in 2004. In contrast, there were four companies with zero leverage and all of them took the IPO in 2001.

It can also been seen on Table 2 above that the average size of the sample firms is around IDR 325 billions with maximum and minimum size of approximately IDR 6,474 billions and IDR 10 billions, respectively. The company that has the largest size was PT Excelcomindo Pratama Tbk and the one with the smallest size was PT Integrasi Teknologi Tbk.

To investigate the use of IPO raised funds by Indonesian firms, this study needs the data from the 53 IPO firms in the final sample to calculate their Working Capital Requirements (WCR), Gross Property, Plant, and Equipment (PPE), Net Liquid Balance (NLB) and Long Term Debt (Leverage) one year before and one year after the IPO. The formulas to calculate those variables are as follow:

PPE   = Gross Property, Plant, and Equipment.
WCR   = Spontaneous Operating Assets – Spontaneous Operating
Liabilities
                = (Accounts Receivable + Inventory + Prepaids) – (Accounts
Payable +
                   Accruals).
NLB   = Cash and Cash Equivalents – Short Term Debt.
                = (Cash + Marketable Securities) – (Notes Payable + Current
Maturities
                   of Long Term Debt).
Leverage   = Long Term Debt / Total Assets.

As in Kim and Weisbach (2005, 2006), the four variables above are measured using the change in each variable normalized by total assets one year prior to the IPO. The formulas are as follow:

$\{V_{T+1} - V_{T-1}\}$ / total assets$_{T-1}$

Where,

V = Variable being measured = WCR, PPE, NLB, or LTD,

T = The IPO year.

3. How Do Indonesian Firms Use Their IPO Raised Funds?

It is mentioned in the Introduction section that the main objective of this study was to empirically examine the motivations of the Indonesian companies in conducting IPO. To investigate motives for Indonesian companies to go public, this study compared the changes in Working Capital Requirement (WCR), Gross Plant, Property and Equipment (PPE), Net Liquid Balance (NLB) and Leverage of IPO firms from one year prior the IPO year to one year after the IPO year. Financial flexibility is represented by NLB and Leverage, while Investment is proxied by PPE and WCR.

As noted by Kim and Weisbach (2005), raising capital has been an important motive in the going public decision of a company. The IPO funds, as a source of equity capital, can be utilized in two forms, first to finance its future growth, and/or secondly, to increase financial flexibility as in enhancing liquidity and in reducing debt. Mikkelson, Partch, & Shah (1997) provide evidence that one of the motivation of a company to go public is to raise equity capital to finance future growth. They documented that US IPOs are generally followed by a large growth in assets. Using a sample of 16,958 IPOs from 38 countries between 1990 and 2003, Kim & Weisbach (2006) also find that the equity capital raised from IPO is used for future investment.

In contrast, a study carried out by Pagano, Panetta, & Zingales (1998) demonstrate that the motivation for Italian companies to go public is not to finance future investments and growth, but rather to rebalance their leverage after a period of high investment and growth. They argue that an Italian

company to go public is to rebalance its leverage in order to increase its financial flexibility. On the other hand, enhancing liquidity is as important as reducing debt in a company's capital structure. Companies may have less debt in their capital structure, but the ability to fulfill its financial obligation when it dues depend on whether or not it has sufficient cash and cash equivalents. To ensure the avoidance of future financial distress, IPO companies may use the raised fund to fortify their liquidity. Regardless the choice of debt reduction or liquidity enhancement, IPO companies can get benefit of avoiding future financial distress, by increasing its financial flexibility.

Table 3
Kolmogorov-Smirnov Tests on the Normality Assumptions on the Changes in Leverage, PPE, NLB and WCR

Variables	*K-S statistics*	p-value
ΔWCR	2.938	0.000
Δ PPE	1.390	0.021
Δ NLB	2.882	0.000
Δ Leverage	2.468	0.000

The model is $\{V_{T+t} - V_{T-1}\}$ / total assets$_{T-1}$. V = variable being measured. WCR is the Working Capital Requirement of the IPO company. PPE is the Gross Property, Plant, and Equipment. NLB is the Net Liquid Balance. Leverage is the amount of Long Term Debt. Δ here represents the difference of the aforementioned variables' figures between one year before and one year after the IPO. The changes in the variables are scaled with total assets at the one year before each IPO.

Table 3 above presents the results of Kolmogorov-Smirnov (K-S) test. This goodness of fit test is performed to determine the normality assumptions of the variables used in this study. As can be seen from the table 3 above, the test has consistently and significantly rejected the null hypothesis at least at the 5% level that the utilization of IPO funds in WCR, PPE, NLB, and Long Term Debt are normally distributed. Accordingly, this result puts forward that one cannot put too much faith on the results from parametric tests, the paired-sample t-test, in this study due to violation of the normality assumption on the data. To overcome that normality problem, a non parametric test, the Binomial test, is employed to gauge the differences in the

variable prior and after IPO. For the shake of completeness, however, the results of the t-tests are also reported below.

Table 4
Univariate Tests on The Changes on WCR, PPE, NLB and Leverage

Variables	Paired-Sample t-test		Binomial Test		
	Mean Difference	t-statistics (p-value)	Observed Proportion		p-value
			Decrease	Increase	
Δ WCR	0.360	2.011 (0.05)	0.19	0.81	0.00
Δ PPE	0.354	4.218 (0.00)	0.25	0.75	0.00
Δ NLB	-0.145	-0.876 (0.38)	0.45	0.55	0.29
Δ Leverage	0.088	1.316 (0.19)	0.34	0.66	0.01

The model is $\{V_{T+t} - V_{T-1}\}$ / total assets$_{T-1}$. V = variable being measured = WCR, PPE, NLB, Leverage. .WCR is the Working Capital Requirement of the IPO company. PPE is the Gross Property, Plant, and Equipment. NLB is the Net Liquid Balance. Leverage is the amount of Long Term Debt. Δ here represents the difference of the aforementioned variables' figures between one year before and one year after the IPO.

Table 4 above presents the results of the t-tests and the binomial tests on the changes in the financial flexibility (NLB and Leverage) and in the Investment (WCR and PPE) one year after the firms conduct their IPOs. Since the violation of the normality assumption on the data, the results of the binomial tests are the basis for the discussions in this section.

Looking at the observed proportion on Table 4 above, the utilization of IPO funds to finance future growth as reflected in the short term investment of Working Capital Requirement (WCR) and in the Property, Plant, and Equipment (PPE) have higher probabilities to have positive values rather than negative values. The p-values for those two variables are significant at less than the 1% level. This indicates strong evidence that IPO companies use their IPO generated fund to finance future growth, both in the forms of WCR and PPE.

In contrast, the utilization of IPO funds to enhance financial flexibility as reflected in the enhancement of Net Liquid Balance (NLB) is not significant at the conventional levels. This indicates that, on average, IPO companies do not utilize their generated IPO fund to enhance their NLBs following the IPOs. When it comes to changes in Long Term Debt following IPOs, an unexpected result emerges. Instead of reduction in Long Term Debt following IPOs, Indonesian firms experience an increase in the Leverage one year after their IPOs . This increase is significant at the 1% levels. This indicates that IPO companies do not seem to use their generated IPO fund to enhance financial flexibility in the form of reducing their long term debt for the purpose of rebalancing their leverage; instead, they rely heavier on the long term debt financing for funding investing activities following their IPOs.

The results of the univariate tests in this study suggest that Indonesian IPO companies utilize their IPO generated fund to finance their future investment, not to enhance their financial flexibility. In addition, instead of reducing their long term debt following the IPOs, these companies even use more long term debt in the post-IPO periods.

4 What are The Factors Affect New Public Listed Firms in Their Investing Decision Following IPOs?

In running their firms on day to day operations, managers may see some potential threat and opportunities to the growth of their firms. Myers and Majluf (1984) argue that in the presence of asymmetric information and limited internally generated funds, a firm may pass up on profitable investment opportunities because of the costs associated with raising external finance. Investigating the investing activities of firms following their IPOs, however, provides a unique

opportunity on the investment behaviour of firms when there is virtually no capital rationing and therefore, no need to raise external financing.

Myers (1977) implies that a firm's assets consists its existing assets and future assets. Although an asset has been existed, it may need a replacement investment to maintain its production power. On the other hand, a future assets calls for either expansion investment if it is in the same industry or a diversification investment if it is in other industries. To further study the investment behaviour of IPO firms following their IPOs, a multiple regression model is employed as follows:

$$\Delta \text{PPE}_i = \beta_0 + \beta_1 \text{Lag PPE}_i + \beta_2 \text{Growth}_i + \beta_3 \Delta \text{Leverage}_i + \beta_4 \text{IPO Fund}_i + \varepsilon_i$$

Where,

ΔPPE_i is the difference in the Gross PPE of an IPO firm i between one year before and one year after the IPO and it is scaled by total asset at the one year before the IPO year. Lag PPE_i the Gross PPE of an IPO firm i at the one year before the IPO year it is scaled by total asset at the one year before the IPO year. Growth_i is the growth opportunity of an IPO firm i, this variable is proxied by the MBA Ratio of a company at the same industry and has the closest amount of total assets with the IPO firm at the one year before the IPO year. IPO Fund_i is total amount raised during an IPO of an IPO firm i. ε_i is an error term. The results of the multiple regression analysis can be seen on Table 6 below:

It can be seen on Table 6 below that the magnitude of pre-IPO firm's PPE has a positive and highly significant influence on a subsequent increase

in PPE following an IPO. The magnitude of the coefficient (0.612) is the largest among the other coefficients. This finding signifies the sensitivity of the investment activities of the post-IPO era to the needs of the firms to rejuvenate their existing PPEs.

Table 6
Relation among changes in PPE, Lag PPE, Growth, Changes in Leverage,
IPO Fund
on 53 IPOs for the Periods of 2000-2005

Independent Variables	Coefficients	t-statistics	p-value (1-tailed)	VIF
Constant	-0.194	-3.23	0.00	-
Lag PPE	0.612	4.74	0.00	1.25
Growth	0.001	5.45	0.00	1.00
Δ Leverage	0.282	2.24	0.02	1.71
IPO Fund	0.391	5.31	0.00	1.79
F-statistics (p-value)	40.64 (0.00)			
Adj. R^2	0.75			

$\Delta PPE_i = \beta_0 + \beta_1 Lag PPE_i + \beta_2 Growth_i + \beta_3 \Delta Leverage_i + \beta_4 IPO Fund_i + \epsilon_i$ Where ΔPPE_i is the difference in the Gross PPE of an IPO firm i between one year before and one year after the IPO and it is scaled by total asset at the one year before the IPO year. $Lag PPE_i$ the Gross PPE of an IPO firm i at the one year before the IPO year and it is scaled by total asset at the one year before the IPO year. $Growth_i$ is the growth opportunity of an IPO firm i, this variable is proxied by the MBA Ratio of a company at the same industry and has the closest amount of total assets with the IPO firm at the one year before the IPO year. $IPO Fund_i$ is total amount raised during an IPO of an IPO firm i. ϵ_i is an error term. The t-statistics, in parentheses, use White's (1980) heteroscedasticity-consistent standard errors. R^2 is the coefficient of determination, adjusted for degrees of freedom. VIF is equal to 1/(1-R2), where R2 is estimated from the regression of an independent variable on all other independent variables. The threshold here is that the data is hampered by Multi-collinearity problems if the VIF value is above 5.

Besides replacement of its existing PPEs, IPO Firms may also need the IPO funds to invest in their growth opportunities of their respective industries. Table 6 above shows that the growth opportunities in each corresponding industry also have a positive influence on IPO firms' decisions for subsequent investment following their IPOs. Although the magnitude of the coefficient (0.001) is the least among the other coefficients. this finding, nonetheless, signifies the decision of the IPO firms to invest in their growth opportunities after going public. This findings also confirm the findings in Chemmanur and Fulgieri (1999), Stoughton, Wong and Zechner (2001), and Maksimovic and Pichler (2001) that, based on the information asymmetric and costly information gathering arguments, firms from particular industries go public because they discover new technology, which leads toward increases in productivity.

The other two variables in the model are the amount of new equity and new debt funding and represent additional sources of financing besides internally generated funds. These funds are the additional funds which were raised during and after the IPOs and, therefore, only available if the firms just went public before. Table 6 shows that the coefficient of the IPO Fund is positive and highly significant at the 1% level. Similarly, the coefficient of the change in the Leverage is also positive and significant at the 5% level. Judging from the magnitude of the both coefficients (0.391 and 0.282 respectively), The IPO firms in this study rely heavier on the equity financing than debt financing to fund their investment in real assets.

The results of the univariate and multivariate analyses on this study then, supports the findings of Mikkelson et al. (1997) who documented that US IPOs are generally followed by a large growth in assets. While Mikkelson et al. (1997) contains no explicit linkage between the companies' growth to the capital raising involved with the IPO, this finding is at least suggestive of the view that companies go public so that they can raise public equity capital to finance growth. The results of this study also support Kim and Weisbach (2006) who examine that one motive for the IPO around the world is to raise capital for investment. The findings in this study, on the other hand, are in contrast with the motivation of Italian IPO companies to rebalance their leverage after a period of high investment and growth as in Pagano, Panetta, and Zingales (1998).

5. Why Does Leverage Increase after IPOs?
Based on the findings mentioned in the previous section, Indonesian IPO firms, on average, increase their leverage following their IPOs. The leverage

in this study is measured relative to their total assets at the one year before

IPOs. Some new investments might need financing from equity, debt, or both.

The funding composition of this new investment depends on each company's

capital structure. Nobel winner Merton Miller and Franco Modigliani (1958)

demonstrate formally that in a perfect capital market the value of a firm

depends only on its investment policy and not on its financing policy. In the

real world, however, there are some factors that influence a fim's capital

structure policy. Several theories have been advanced to propose those

factors and their impacts on a firm's leverage have been tested empirically

both in the US and International settings (Harris and Raviv, 1991; Rajan and

Zingales, 1995; Shyam-Sunder and Myers, 1999; Graham and Harvey,

2001).[82]

To investigate further on the relationship between changes in leverage

and the amount of funding raised in IPOs, a multiple regression analysis is

employed as follows:

$$\Delta \text{Leverage}_i = \beta_0 + \beta_1 \text{Size}_i + \beta_2 \text{Profitability}_i + \beta_3 \text{Growth}_i + \beta_4 \text{IPO Fund}_i + \varepsilon_i;$$

Where,

$\Delta \text{Leverage}_i$ is the difference in Long Term Debt of an IPO firm i between one

year before and one year after the IPO and it is scaled by total asset at the

one year before the IPO year. Size_i is the natural log of total assets of an IPO

---

[82] The most notable theories on factors affecting firm's target leverage are the ones based on the trade-off theory and the pecking order theory.

firm i at the one year before the IPO year. Profitability$_i$ is the ROA of an IPO firm i for one year before the IPO year. Growth$_i$ is the growth opportunity of an IPO firm i, this variable is proxied by the Market to Book Asset ratio (MBA) of a company at the same industry and has the closest amount of total assets with the IPO firm at the one year before the IPO year. MBA Ratio = Market Assets / Book Assets = {(share price × shares outstanding) + preferred stock + debt in current liabilities + long-term debt – deferred taxes and investment tax credit} / Book value of assets. IPO Fund$_i$ is total amount raised during an IPO of an IPO firm i. ε_i is an error term. The results of the multiple regression analysis can be seen on Table 5 below.

Table 5
Relation among Changes in Leverage, Size, Profitability, Growth and IPO Fund
on 53 IPOs for the Periods of 2000-2005

Independent Variables	Coefficients	t-statistics	p-value (1-tailed)	VIF
Constant	-4.231	-3.04	0.00	-
Size	0.163	3.04	0.00	1.11
Profitability	-0.148	-2.89	0.01	1.07
Growth	-0.001	-0.22	0.41	1.00
IPO Fund	0.342	1.77	0.04	1.04
F-statistics (p-value)	12.56 (0.00)			
Adj. R^2	0.47			

Δ Leverage$_i$ is the difference in Long Term Debt of the IPO firm between one year before and one year after the IPO scaled by total asset at the one year before the IPO year. Size$_i$ is the natural log of total assets of the IPO firm at the one year before the IPO year. Profitability$_i$ is the ROA of the IPO firm for one year before the IPO year. Growth$_i$ is the growth opportunity of an IPO firm, this variable is proxied by the Market to Book Asset Ratio (MBA) of a company at the same industry and has the closest amount of total assets with the IPO firm at the one year before the IPO year. IPO Fund$_i$ is total amount raised during the IPO. ε_i; is an error term. The t-statistics, in parentheses, use White's (1980) heteroscedasticity-consistent standard errors. R^2 is the coefficient of determination, adjusted for degrees of freedom. VIF is equal to $1/(1-R^2)$, where R^2 is estimated from the regression of an independent variable on all other independent variables. The threshold here is that the data is hampered by Multi-collinearity problems if the VIF value is above 5.

It can be seen on Table 5 above that there is a positive relationship between the amount of funds raised in the IPOs and the decision to increase leverage at the one year after the IPOs. This relationship is significant at the 5% level.

As mentioned earlier, some new investments might need financing from equity, debt, or both. Assuming that, on average, the new investment calls for funding from the combination of equity and debt. After raising external equity funding through IPO, these IPO companies also issue new debt afterwards.

IPO raised funds might also be used as a safety cushion and this new safety net attracts lenders to extend credits for the companies since they believe that by having more cash, these companies have increased their level of credit worthiness in the debt engagement. This leads to these companies having a greater bargaining power with banks and other lenders in issuing new debt.

To elaborate more, a potential problem with bank loans is that banks can extract rents from their privileged information about the credit worthiness of their customers. As highlighted by Rajan (1992), by gaining access to the stock market and disseminating information to the generality of investors, a company elicits outside competition to its lender and ensures a lower cost of credit, a larger supply of external finance, or both. Moreover, having a prestigious status as public companies might also help in obtaining new debt from lenders.

As stated by Pagano, Panetta, and Zingales (1998), the most cited benefit of going public is probably the increased likelihood of those companies to gain more access to capital markets both equity and debt markets. In other words, the status as public companies can be said to overcome the borrowing constraints of the companies. Hence, firms go public to raise equity financing and, afterward, increase their debt financing following the IPO. These IPO

companies must be fund-hungry companies that seek for plenty of fresh funds to fuel their future investment.

Based on the trade-off theory of the capital structure, a firm's target leverage is positively influenced by taxes and negatively influenced by costs of financial distress and agency conflicts. Warner (1977) and Ang, Chua and McConnel (1982) find that costs of financial distress are higher for smaller firms. With regard to probability of going into bankruptcy state, Titman and Wessels (1988) argue that larger firms tend to fail less often due to their diversification nature of their operations. Diversification may also go hand in hand with more stable cash flows as implied by Jensen (1986) and Easterbrook (1984). Accordingly, the theory predicts a positive relationship between size and leverage. Table 5 above shows that there is a direct relationship between Leverage and Size. This positive relationship is significant at less than the 1% level.

The trade-off theory also prescribes a positive influence of taxes and a negative influence of financial distress costs and agency conflicts on a firm's target leverage. Profitable firms have lower probability of going into bankruptcy state. With tax deductibility feature of debt services, profitable firms also find themselves in the position to take fully advantage of that benefit. In addition, higher debt may control the agency problems by forcing managers to pay out more of the firm's excess cash as suggested by Jensen and Meckling (1976), Easterbrook (1984), and Jensen (1986). Therefore, the theory suggests a positive relationship between leverage and profitability.

With regard to the relationship between leverage and profitability of Indonesian IPO firms in this study, Table 5 shows a negative and significant

relationship between profitability at the one year before IPOs and the decision to seek more debt financing at the one year after their IPOs .This result is in conflict with the one predicted by the trade-off theory. The pecking order theory, on the other hand, argues that firms prefer raising capital, first from retained earnings, second from borrowing, and finally from issuing new equity. This order of preferences is due to the direct and indirect costs of floating new shares in the presence of information asymmetries. Compare with less profitable firms, highly profitable firms is more likely to have its investment needs less than its retained earnings. Consequently, the pecking order theory prescribes a negative relationship between leverage and profitability. The finding in this study, therefore, more in line with the pecking order theory than the trade-off theory of capital structure.

In contrast with the other variables, Table 5 shows that there is no significant relationship between growth opportunities and leverage. Myers (1977) demonstrate that the market value of a firm depend on the value of its assets in place and present value of growth opportunities facing by the firm. A growth firm has its market value consists mainly from its present value of growth opportunities. Accordingly, the theory predicts that firms with higher growth carry less debt in their capital structure because they face less incentive to reduce conflicts between stockholder-bondholder due to underinvestment and asset substitution effects (Galai and Masulis, 1976; Jensen and Meckling, 1976). Moreover, Jensen (1986) argues that firms with higher growth opportunities have less need for the disciplining effect of fixed payments to control their free cash flows. Consequently, it is predicted that there is a negative relationship between growth opportunity and leverage.

Previous empirical studies, however, find that results on the relationship between growth opportunities and leverage are mixed, at best. A study conducted by Titman and Wessels (1988) find a negative relationship, while by Rajan and Zingales (1995) find an opposite results that the relationship is positive report a positive relationship between leverage and growth. The finding on this study that there is no relationship between growth opportunities and leverage may the results of the negative and positive effects of growth opportunities on the leverage cancel each other out.

6. Concluding Remarks

The objective of this study is to empirically examine the motivations of the Indonesian companies in conducting IPO. It is found that Indonesian IPO companies utilize their IPO generated fund to finance their future investment, not to enhance their financial flexibility. In addition, instead of reducing their long term debt following the IPOs, these companies even use more long term debt in the post-IPO periods. However, the IPO firms in this study rely heavier on the equity financing than debt financing to fund their investment in real assets. The results of this part of the study supports the findings of Mikkelson et al. (1997) and Kim and Weisbach (2006) that the motive for the companies to go IPO is to raise capital for investment.

Further investigation reveals that that there is a positive relationship between the amount of funds raised in the IPOs and the decision to increase leverage at the one year after the IPOs. The increase in leverage might be a necessity for keeping capital within an optimal range in the face of new post-IPO investment activities. Having a prestigious status as public companies

might help in obtaining new debt from lenders. IPO raised funds might also

be used as a safety cushion and this new safety net attracts lenders to extend

credits for the companies since they believe that by having more cash. These

lead to these companies having a greater bargaining power with banks and

other lenders in issuing new debt.

MARKET REACTION TO THE ANNOUNCEMENT OF RELATED PARTY TRANSACTIONS

Sidharta Utama, Cynthia A. Utama, Rafika Yuniasih, Universitas Indonesia

Abstract

This study investigates stock market reactions to firms' announcements of related party transactions ("RPT") in Indonesia. RPT can result in either positive or negative stock price reaction. The reaction is positive when the market expects that RPT is more efficient than Non-RPT while it is negative when the market perceives RPT as a way to expropriate wealth of non-controlling shareholders. This study also investigates whether the effect of RPT on stock market reaction depends on corporate governance practice, ownership structure, and disclosure level. Empirical study on corporate announcements in 2005 – 2007 finds a more positive reaction toward RPT than non-RPT, suggesting that in general RPT provides a more efficient way to conduct transaction than non-RPT. The study also finds that higher disclosure level magnifies the positive stock price reaction toward RPT.

Keywords: related party transaction, market reaction, corporate governance, ownership structure, disclosure level

1. Introduction

The extent of stock market growth in a country depends on the existance of equitable treatment of all shareholders, including minority and foreign shareholders, regardless of their ownership level. The practice of equitable treatment of all shareholders is one of the principles of corporate governance (*Organization for Economic Co-operation and Development* (OECD), 2004).

In Indonesia, and in several countries in Asia, many listed companies have ownership structures that are still concentrated. Majority shareholder owns a large portion of company's outstanding shares and have controlling interest over the company. On the other hand, the level of public ownership is relatively low. Further, majority shareholder typically also controls other firms and this condition increases potential occurance of related party transactions ("RPT"). RPT under IAS 24, is *".. a transfer of resources, services, or obligations between related parties, regardless of whether a price is charged."* (IAS 24, par. 9).

RPT can have a positive or negative impact on firm performance (Gordon, Henry and Palia, 2003). The efficient transaction hypothesis. suggests that RPT can fulfill basic economic need of a company by lowering cost of transaction so that company can be more efficient. RPT has its own positive influence in the day-to-day business operation and to the general economy. Assurance to the occurrence of RPT is relatively high compared to those of third party transactions. Further, since the transaction is under common control, transaction cost of RPT is also lower than those of third party transactions. Having these two reasons, it is no surprise that companies, especially those under common control, commonly conduct RPT.

On the other hand, the conflict of interest hypothesis pertain to RPT as transactions with the tendency toward expropriation of minority shaholders' wealth. This kind of RPT usually occur in companies with low corporate governance mechanism and low adjusted stock return. Consistent with the hypothesis, McCahery and Vermeulen (2006) conclude that even though RPT can play a positive role for companies, fraudulent and abusive RPT may exist whereby controlling shareholders' wealth is maximized at the expense of minority shareholders. A study by Johnson, et.al. (2000) find that in companies with concentrated ownership, majority shareholder can expropriate the wealth of minority shareholders in many ways. They can gain additional cash by selling assets, goods, or services to the company trough RPT at prices above the market prices; they can obtain loans with agreeable terms; they can transfer assets between companies under their control; and at worse, they can dilute the ownership of minority interest.

Consistent with these two opposing views, Cheung, et.al. (2006) classify RPT into: i) transactions that are a priori likely to result in expropriation of company's minority shareholders, ii) transactions likely to benefit company's minority shareholders, and iii) transactions that could have strategic rationals and perhaps are not expropriation.

Transactions between related parties that include asset acquitistions, assets sales, equity sales, trading relationships, and cash payment are viewed as transactions with potential effect to result in an expropriation of the wealth of minority shareholders. Transactions, such as cash receipts and subsidiary relationships are viewed as the opposite: they most likely will benefit the minority shareholders. Other transactions, such as takeover offers and joint ventures, joint venture stake acquisitions, and joint venture sales are classified as strategic transactions that may not have expropriation effect.

The expropriation view of RPT is supported by some studies that find a negative market reaction to the announcement of related party transactions. A study by Bae, Kang, Kim (2002) in Korea empirically shows a negative reaction. In Korea, chaebols (business groups) are very dominant in the economy and some public companies belong to the chaebols, which typically are controlled by certain families. Furthermore, Bae, Kang, Kim (2002) find that acquisition between companies under the same chaebol will decrease the market prices of the acquirees, which are primarily owned by minority shareholders; while evidence also shows an increase in the value of acquirors which are mostly owned by majority shareholders.

In Hongkong, a study by Cheung, et.al. (2006) also find a significantly negative excess return on RPT announcements relative to Non-RPT announcements. This study provides direct support on the existence of expropriation of minority shareholders' wealth. Minority shareholders' wealth decreases significantly when companies decide to have RPTs.

In Indonesia, empirical studies on RPT are rare. Studies by Masturoh (2000) and Santoso (2003) evaluate market reaction to the announcement of internal

acquisitions, especially those with divergence between control and cash-flow rights. Disparity between cash-flow rights and control rights motivates controlling shareholders to make acquisitions that increase their own wealth at the expense of minority shareholders. Masturoh (2000) find a negative abnormal return for firms with internal acquisition, while Santoso (2003) find evidence of negative cumulative abnormal return for the acquirer.

A later study by Utama (2006) focuses on RPT in connection with investment decisions. This study finds a weaker market reaction to the announcements of RPT compared to those of non-RPT. This evidence show that market views RPT as more vulnerable to the possibility of expropriation of minority shareholders' wealth. It also finds a weaker market reaction to the announcement of firms belonging to a business group than independent firms.

As mentioned earlier, Gordon, Henry, and Palia (2003) view RPT as transactions that can actually result in two different market reactions: negative and positive. Negative market reaction to the announcement of RPT support the conlict of interest hypotheses of RPT while positive reaction of RPT announcement is possible under the efficient transaction hypotheses of RPT: The study summarizes that market views RPT as a more efficient transaction than non-RPTs; reducing the need for more monitoring.

To mitigate expropriation and negative impact of RPT, the capital market regulatory body in Indonesia, i.e. Badan Pengawas Pasar Modal – Lembaga Keuangan or Bapepam-LK, issues several regulations to protect the interest of minority and other shareholders. Such regulations include those on disclosures and corporate governance.

Bapepam Regulation No. X.K.1 requires all listed companies in Indonesia to report every transactions (including RPT) that materially affects the company's value, including investment decisions. While regulation No. IX.E.1 about conflict of interest transactions requires certain transactions to have approval from minority shareholders, including the disclosure of the transactions. Further, regulaion No. VIII.G.7 provides guidance as to how listed companies should present and disclose RPT. Other regulatory body, the Indonesian Chartered Accountants, issues Indonesian Financial Accounting Standard (PSAK) No. 7 about disclosure of related parties. This standard requires listed companies to disclose related parties and transactions among them. Bapepam-LK also requires listed companies to have at least 30% of members of the supervisory board to be independent commissioners and to establish audit committee.

With those regulation already in effect in Indonesia, the most important question is whether or not they are sufficient to address the negative impact of RPT? How about their implementation and effectiveness?

In addition to that, further study is warranted in the following area:

- Studies in Indonesia only cover investment decisions, while RPT involve more than investment decisions.
- The effect of disclosure on RPT, corporate governance, and ownership structure on market reaction toward RPT announcement.

The result of the study can also be used to evaluate implementation and effectiveness of RPT regulation.

Therefore, the objectives of the study are: i) to evaluate the implementation and effectiveness of RPT regulation; and ii) to investigate stock market reactions to firms'

announcements RPT in Indonesia and if the reaction depends on the level of RPT disclosure, corporate governance, and ownership structure.

2. Research Design and Hypothesis Development

Evaluation of the implementation and effectiveness of RPT regulation in Indonesia is done by having a Focus Group Discussion (FGD). This FGD involves regulatory body (the Bapepam-LK), experts in capital markets, experts in corporate governance, and academicians.

The FGD is based on instrument developed by the OECD to measure the application of corporate governance principles, especially its adoption to regulation, in relation to the protection of minority shareholders. Furthermore, other relevant regulations on information and public disclosure are gathered in order to help answering the questionnaire. We also did some research to evaluate similar regulations in neighboring countries, such as Malaysia, Thailand, Singapore, Hong Kong, the Philippines, and South Korea, and their applications.

Analysis on the relationship of RPT and market reaction is conducted by using several variables, i.e. market reaction, RPT classifications, corporate governance practices, RPT disclosures, and ownership structures. Market reaction is measured by Cummulative Abnormal Return (CAR) around announcement dates for 3 days event windows (day -1 to day +1). Market adjusted return is used in calculating the daily abnormal return. Announcements of material transactions are classified into those of RPT and those of non-RPT. A dummy variable (DRPT) takes the value of one if the announcement involves RPT, else zero. Corporate governance practice is measured by CG Score developed by the Indonesian Institute for Corporate Directorship (IICD). The score is based on an instrument covering five components of

Corporate Governance (CG) principles suggested by the Organization of Economic Cooperation and Development (OECD). The instrument consists of 117 items. Each item is rated 'poor' (scored one), 'fair' (scored two), and 'good' (scored three) depending on whether the item is properly practiced based on information publicly disclosed in 2005. The total CG score is calculated as a weighted average of the score of each component. RPT disclosure is represented by the availability of value of transaction in the announcement. A dummy variable (DDISCL) takes the value of one if the announcement provides information on the value of the transaction, else zero. Ownership structure is measured by the percentage of majority ownership, management (board of directors) ownership, and foreign ownership. As a control variable, the study employs company size,. measured by the log of firm's market capitalisation.

Hyptheses development

As discussed earlier, RPT has two contradictive nature. It can be viewed as transaction with expropriation potentials resulting in negative market reaction, but it can also be viewed as an efficient transaction that can lower costs, resulting in postive market reaction. Because of that, market reaction to RPT announcement can be either positive or negative:

H1: RPT announcement can have a positive or negative relation to the cummulative abnormal return

Further, the study expects that market reaction to the announcement of RPT is affected by the practice of corporate governance in the company, the level of disclosure in each announcement, and the ownership structure. If the practice of corporate governance is good, it will enhance supervision and monitoring of RPT, so

618

that at the end, RPT that actually occurrs more likely is RPT that increases effectiveness and efficiency of the firm. Therefore, higher CG Score should result in more positive market reaction toward RPT relative to Non-RPT announcement.

H2: The relation between CAR and RPT announcement is more positive if CG Score increases

Disclosure of the value of transaction is a proxy of overall disclosure of transaction. Higher disclosre in the announcement of transaction shows company's good intention to provide information and assure sufficient disclosure to shareholders and other stakeholders. If the intention of the transaction is for efficiency reason, then there is nothing to hide, with the consequence of higher disclosure level. As a result, disclosure of the value of transaction should result in more positive market reaction toward RPT relative to Non-RPT announcement.

.

H3: The relation between CAR and RPT announcement is more positive with disclosure of value of transaction.

The increase of ownership interest by majority shareholders and by board of commissioners increase the control right as well as cashflow right of the majority shareholders. Accordingly, higher control right makes them easier to conduct RPT. As discussed earlier, RPT can result in positive or negative market reaction depending on how market evaluates the RPT. Market can evaluate RPT as a tool to expropriate minority shareholders' wealth or to increase efficiency and effectiveness of operations.

H4: The relation between CAR and RPT announcement is influenced by ownership interest of majority shareholders.

H5: The relation between CAR and RPT announcement is influenced by ownership interest of the board of commissioner

Assuming foreign investors are more sophisticated than domestic investors in term of their monitoring ability, the existence of foreign investor in a company will increase monitoring and supervision on RPT so it is more likely that RPT occurring is the one that increases the efficiency of company's operation. Thus, higher foreign investors ownership should result in more positive market reaction toward RPT relative to Non-RPT announcement.

H6: The relation between CAR and RPT announcement is more positive with the increase in ownership interest of foreign investor

Sample selection

Unit analysis in this study is listed company with corporate action during the period of 2005 – 2007. Corporate action data is obtained from Indonesian Stock Exchange, data is also gathered from Bisnis Indonesia. Criterias for sample selectrion are:

- Companies listed in Indonesian Stock Exchange

- Companies with corporate action

- Corporate action can be identified as RPT or non-RPT and with or without transaction amount

- Available share prices during the event windows

- Available financial statement and annual report

- Available ownership data from financial statement

Corporate action identification

- This study covers only types of corporate actions that has the potentials for RPT, i.e: Annual Shareholders's Meetings (ASM), result of the ASM, Issuance of shares without preemptive rights, Disclosure on issuance of shares without preemptive rights, Short prospectus on issuance of shares, Tender offer, Merger, and Material Transaction.

Regression Model

The empirical model to test the hypothesis is as follow. To control for heteroscedasticity, the regression is run using White heteroscedasticity consistent covariance matrix.

$$CAR_i(k,l) = b_0 + b_1 DRPT_i + b_2 CGI_i + b_3 DDISCL_i + b_4 PROP_i + b_5 BOC_i + b_6 DFOR_i +$$
$$b_7 CGRPT_i + b_8 DDISCLRPT_i + b_9 PROPRPT_i + b_{10} BOCRPT_i +$$
$$b_{11} DFORRPT_i + b_{12} LOGMKT_i$$

CAR	=	market reaction to corporate action announcement
DRPT	=	types of transaction (dummy; 1=RPT, 0=non RPT)
CGI	=	CG Score
BOC	=	ownership interest of the board of commissioners
DDISCL	=	disclosure of the amount of transaction (dummy; 1=disclosing the amount, 0=not disclosing the amount)
PROP	=	ownership interest of the majority shareholders
DFOR	=	foreign ownership (dummy; 1=majority shareholder is a foreign company, 0=majority shareholder is a domestic company)
CGRPT	=	interaction of CG and DRPT

BOCRPT   =   interaction of BOC and DRPT

PROPRPT =   interaction of PROP and DRPT

DFORRPT =   interaction of DFOR and DRPT

DDISCLRPT   =   interaction of DDISCL and DRPT

LOGMKT   =   size (as a control variable)

In addition to including CGI, BOC, DDISCL, PROP and DFOR as moderating variables,, the study also includes them as independent variables. A study by Black (2001) states that CG practice has a positive relation to value of the firm. Thus, higher CG score may result in higher CAR.CG principles require accurate and timely disclosure of company's information such as financial position, performance, ownership structure, corporate governance application, and RPT. Higher disclosure reduces the degree of asymmetric information which may result in higher CAR. A study by Capulong et.al. (2000) states that in company with highly concentrated ownership, majority shareholders have a significant role in supervising the management, that will be positively responded by the market. But as the ownership gets more concentrated, it will increase the ease with the majority shareholders can authorize an RPT. This condition can have dual effect to market reaction. The same goes to management ownership. Lastly, it is commonly known that foreign ownership increases supervision and monitoring, that will be positively responded by the market.

3. Result and Discussion

Size of RPT in Indonesia

Analysis on the financial statements of listed companies in the Indonesian Stock Exchange during 2005 – 2007 shows that transactions involving related parties are quite substantial relative to the book value of equity. The data are as follow:

- Ratio of RPT assets and RPT liabilities compared to total equity:

  – 42% in 2007, 48% in 2006, and 43% in 2005

- Ratio of RPT sales and RPT expenses compared to total equity:

  – 87% in 2007, 65% in 2006, and 84% in 2005.

Based on the above statistics, we can conclude that RPT is relatively high in listed companies in the IDX. Considering that listed companies in Indonesia mostly have highly concentrated ownership, this result provides evidence that the degree of concentration of ownership structures affects frequency and size of RPT.

Analysis on RPT regulation in Indonesia[83]

Regulation about RPT in Indonesia focuses on several key issues:

- Public companies are required by Bapepam-LK to disclose information on RPT in audited Financial Statements. Details that should be disclosed include:

  o Assets, liabilities, sales, and purchases that involved RPT and their percentage to total assets, total liabilities, total sales, and total purchases

  o If transaction amount or ending balance of the above-mentioned account is more than one billion rupiahs, the amounts or balances should be disclosed separately and relation with that specific party mentioned.

  o Character, nature, and components of RPT.

  o Pricing policies and transaction requirements, and information whether or not the pricing policies and transaction requirements are similar with those of third parties

  o Reasons and assumptions on the creation of allowance for doubtful account to RPT receivables.

---

[83] For a more in-depth analysis with Indonesia's experience with managing RPT, please refer to Utama (2008).

- Certain RPT that involves conflict of interest should gain approval from the independent shareholders before it can be done.

- Listed companies should provide disclosures and information, especially on significant RPTs and on RPTs with conflict of interest

- The new company law in 2007 (Undang-Undang No. 40 Perseroan Terbatas) requires directors/commissioners that are involved in conflict-of-interest transaction cannot decide/approve the transaction. The approval should come from other directors/commissioners who are not involved with the transaction. If all directors/commissioners are involved, then shareholders should appoint an independent party to make decision regarding the transaction.

- The company law also enables minority shareholders to file lawsuit against director/commisioner/company for a loss caused by negligience or intentional fraud. Directors/ Commissioners / Controlling shareholders may also personnaly liable they abuse their power to to their advantage at the expense of other parties such as minority shareholders.

Based on our analysis, the RPT regulation in Indonesia has provide adequate protection for all shareholders against potential negative effects of RPT. Indonesia is the only country in Asia that requires approval from independent shareholders in the case of RPTs with conflict of interest.

With regard to firms' compliance to disclosure requirement, the study analyzes the level of RPT disclosure based on the disclosure requirement by Bapepam-LK explained earlier. There are 10 items to be disclosed and each item is checked whether it is disclosed or not. A score of one is given if it is disclosed, zero otherwise. Thus, if firms disclose all items, the maximum score will be ten. The results are as as follow:

- RPT Disclosure in Financial Statements:

  – 81,23% in 2007, 78,9% in 2006, and 79,88% in 2005

The results indicate that the level of compliance to RPT disclosure requirement is relatively good. However, not all disclosure items are complied. Majority of the firms (more than 50%) did not disclose pricing policies and transaction requirements of RPT, while the information is crucial for investors to evaluate the fairness of the transactions.

With regard to independent shareholders approval, between 2001 – 2007 there were approximately 70 transactions obtained independent shareholders, which were relatively small compared to the size of RPT transactions in Indonesia. Thus, the approval processes of majority of RPT during the period were up to the firms. After the enactment of company law in 2007, companies have to follow the article with regard to conflict-of-interest transaction; thus, the impact of this law on RPT remains to be seen.

Further, RPT regulations in Indonesia are not without flaws. The regulations are lacking in term of empowerment and legal support toward their implementation. Indonesia do not have special body or court that can put on trial a company that is proven to have violate the regulations. From this point of view, Indonesia is still behind other coutries in Asia such as Malaysia, Taipei, Thailand, and Vietnam.

Sample

From a total of 2,449 corporate action in 2005 – 2007, only 716 fulfill the requirements of RPT and non-RPT identifications. After that, the selected samples is further analysed based on redundancy and RPT potentials. This second filtering provides us with 177 RPT samples and 190 non-RPT samples. After data availability consideration, we gathered a final sample of 148 corporate actions, 70 of which are RPTs and the rest (78 samples) are non-RPT.

Empirical Results

The following table provides statistic descriptive of the dependent and independent variables.

Table 1. Statistic Descriptive

	CAR	*DRPT*	*CGI*	*DDISCL*	*PROP*	*BOC*	*DFOR*	*LOGMKT*
Mean	-0,004	0,473	0,629	0,432	0,499	0,331	0,385	11,554
Standard Error	0,011	0,041	0,006	0,041	0,013	0,017	0,040	0,109
Median	-0,004	0,000	0,625	0,000	0,510	0,333	0,000	11,745
Standard Deviation	0,135	0,501	0,074	0,497	0,160	0,201	0,488	1,326
Sample Variance	0,018	0,251	0,005	0,247	0,026	0,040	0,238	1,757
Minimum	-0,570	0,000	0,490	0,000	0,074	0,000	0,000	4,834
Maximum	0,676	1,000	0,837	1,000	0,949	0,857	1,000	13,521
Count	148	148	148	148	148	148	148	148

The average CAR is 0.4% and is not significantly different from zero. Thus, on average the market does not react to corporate announcements. The occurrence of RPT (DRPT) has mean value of 0.473; from 70 out of the total sample of 148. This indicates that almost half of corporate actions are RPTs. Considering the nature of ownership structure of companies in Indonesia, the result is not surprising. The

average CG practice is 62.9%, indicating that CG practice in Indonesia is still relatively inadequate. For the occurrence of disclosure of corporate action (DDISCL), the mean value is 0.432; with 64 companies out of the total sample 148 provide disclosure of value of transactions on corporate action. Value of transaction is one key information needed by investors to evaluate the impact of the transaction to firm value, thus, this result shows an inadequate transparancy of listed firms in IDX.

The proportion of majority ownership in companies in Indonesia (PROP) has a mean value of 49.9%, with minimum and maximum amount of 7.4% and 94.9%, respectively. This result is, again, not surprising, and showing that the tendency of ownership structure in companies in Indonesia leans toward high percentage of majority ownership. Ownership interest of the BOC averages around 33.1% with minimum and maximum amount of 0 and 85.7%, respectively. The table also indicates that from total sample 148, 64 of them have a foreign majority ownership.

Table 2 provides correlation analysis among variables. All independent variables do not have significant correlation with CAR. CGI has a positive correlation with DRPT, a negative correlation with BOC, and a positive correlation with LOGMKT. The positive correlation with DRPT is quite a surprise; however, if majority of RPTs are for efficient purpose, then the positive correlation should be expected. Proportion of ownership by majority shareholder (PROP) has a positive correlation with DRPT, suggesting that higher ownership makes it easier for majority shareholder to conduct RPT. As expected, PROP also has a positive correlation with BOC.

Study by Gordon, Henry, dan Palia (2003) states two hypotheses for the nature of RPT. The first hypotheses, the conflict of interest hypotheses, claims that RPT is a transaction with tendency toward expropriation of minority shareholders' wealth. The second hypotheses, the efficient transaction hypotheses, claims that RPT can fulfill basic economic needs of corporation with its ability to decrease cost of transactions. Hypotheses of this study is RPT announcement can have a positive and negative market reaction

Result from table 3 supports the efficient transaction hypotheses. There is a positive and significant relation between RPT announcement and market reaction to that announcement at 5% significance level. With this result, we can conclude that in general market reacts positively toward RPT announcement because they view RPT as transaction to be more efficient than Non-RPT and thus can increase value of the firm. The finding is contradictory to the findings of Utama (2006) and Masuroh (2000) who find a relatively more negative reaction toward RPT than Non-RPT. There are several plausible reasons for this contradictory results:

1. The period of studies of Masuroh (2000) and Utama (2006) covers earlier years (before 2005) than the current study. There may be structural changes (e.g., more regulation, more stringent enforcement) over time that may affect the results. Thus, this possibility warrants further research that cover longer period.

2. This study covers broader corporate action than their studies, which are limited only to investment decisions. This may imply that non-investment decisions are less likely to be employed as means to expropriate than investment decisions.

Table 3 also provides evidence of a positive and significant relation between DDISCLRPT and CAR, supporting hypothesis 3. Disclosing the value of transaction

indicates management's good intention of transparency toward shareholders and other stakeholders. Disclosing the value of transaction also reduces asymmetric information regarding the transaction. Therefore, market reaction to the disclosure is positive.

The study finds that corporate governance practice does not have any impact on the relation between RPT and CAR, as shown by the insignificant coefficient of CGRPT. The result suggests that in Indonesia, corporate governance practice is not yet effective in controlling RPT that might be detrimental to a firm. However, one reason that may explain the insignificant result is the measurement of CG practice. As mentioned earlier, CG Score is based on five principles of Corporate Governance, including the principle of taking into account the interest of stakeholders. This principle is not related to the internal control mechanism in a firm, including internal control related to RPT. Thus, future study may need to come up with a more refined measure of CG that covers only internal control of a firm.

All ownership structure variables are not significant, implying that ownership structure does not have any role in controlling RPT.

4. Conclusion

With regard to regulation on RPT in Indonesia, we conclude that in general the regulation is relatively adequate. The regulation includes

- Listed companies in Indonesia is obliged to disclose detail RPT information in Financial Statement
- RPT with conflict of interest should gain approval parties not involved with the transactions.
- Certain RPTs require approval from independent shareholders.

- Directors/Commissioners/Controlling Sharholder can be held personally liable for causing loss to a firm/minority shareholders as a result of RPT transaction.

- Under certain condition, minority shareholders may file lawsuit against directors/commissioners/controlling shareholders for any wrongdoing.

However, Indonesia still lacks legal empowerment against violation of RPT and CG regulation.

The study finds that in general, market views RPT as more beneficial than non-RPT. Further, market appreciates more disclosure on RPT. Thus, the study recommends regulatory body to enforce the compliance of listed firms to disclosure requirement. On the other hand, we also find that CG practice is not yet effective in controlling RPT and ownership structure does not have any effect on the nature of RPT.

The study has some limitations that deserve mention. The study covers only three years, thus future study needs to extend the period of the study. The proxy for CG practice may be too broad so it does not capture the role of CG in controlling RPT. Therefore, future studies may need to develop a more refined measure of CG. Future study may also need to distinguish RPT into several types as suggested by Cheung (2006) and test whether the reaction is contingent upon the types of RPT. RPT may also be categorized into type of business decisions, such as investment, financing, or operating decisions and future study may investigate whether the type of business decision affects the market reaction.

PRIVATE INFORMATION ARRIVAL AT INDONESIA STOCK EXCHANGE, REALITY OR IMAGINARY? U-SHAPED RETURN VARIANCE CURVE VERIFICATION

Setiyono Mihardjo,[*] and S u m i y a n a
Universitas Gadjah Mada

Abstract

This research investigates occurrence of private information arrival in the Indonesia Stock Exchange (IDX). The occurrence comes from overnight nontrading session as well as lunch-break hour. Lunch-break return variance decrease negatively two times in comparison with early morning and lately afternoon return variances. This variance is not due to public information arrival because public information flows did not change stock prices. Based on microstructure theory, this morning return variance was affected by private information or mispricing.

This study finds that opening prices form the full day U-shape. It means that opening price causes mispricing's stock. It also be concluded that the occurrence are considerably caused by relevant asymmetric information. In addition, lunch-break session produces the bottom line on the U-shape to move downward. Therefore, the movement implies the existence of private information that is short-lived.

Keywords: *U-Shaped, private and public information, asymmetric information*

JEL Classification: G-11, G-14, M-41

1. Introduction

A research has confirmed that price variance or return volatility is always highly fluctuating between morning and afternoon trading period in IDX (Sumiyana, 2007; 2008). This study continues the research above by a question "why does return volatility increase during every trading period in IDX?" Some previous research have tried many times to answer the questions which end up in price formation theory (French & Roll, 1986; Harris, 1986; Wood, McInish & Ord, 1985; Jain & Joh, 1988; McInish & Ord, 1990; Amihud & Mendelson, 1991; Peiers, 1997; Huang, Liu, & Fu, 2000; Steeley & Chelley, 2001). The inference obtained from those studies shows that there are three possibilities causing the high movement of return volatility. The first is public information that generally comes during trading sessions. Second, private information drives the trading which influences the price change during trading period. Third, error in pricing may occurs during trading period. Furthermore, French & Roll (1986) stated that the first and third reason is denied because public information arrival does not change stock prices.

Additionally, pricing error is founded with very low probability. Therefore, the main cause of high return volatility is only private information.

More substantially, in order to prove price formation theory, we design this study using formula of intra hour's day of the week as conducted by Amihud & Mendelson (1987), Stoll & Welley (1990), Huang, Liu & Fu (2000), and Guner & Onder (2002). Amihud & Mendelson (1987) stated that return variance during open-to-open period is greater than close-to-close period. Stoll & Welley (1990) derived the same conclusion as Amihud & Mendelson (1987) research, but confirmed that their research is consistent with trading mechanism hypothesis. Huang, Liu & Fu (2000) developed research that investigates empirically that returns variance during trading period is greater than return variance during nontrading period. Similarly, Guner & Onder (2002) stated that private information is submitted by informed traders during a trading period, so that private information tends to directly influence the return during trading. As a result, volatility during trading period is higher than volatility during nontrading period. This research proves that this private information hypothesis does correct.

The examination of private information phenomenon which is really occurring especially in IDX is conducted within two stages in this study. In the first stage, the study conducts examination by comparison of the return volatility between trading periods and inter trading period simultaneously on assumptions that public information flow does not change. In the second stage, this research examines the result of the first stage in more in-depth way to support private information hypothesis. The examination is conducted in series formulation that U-Shaped volatility is built. The confirmation of U-Shaped volatility is sharpened in lunch break which is suspected with the lowest return variance. Later, the movement of return variance is inversely lessened, which means moving upward to the upper right after lunch break. This series can be interpreted that private information which come to the traders during morning trading period has been corrected after the opening of day trading session. This correction is marked by the fall of return variance after the opening trading session.

The existence of U-Shaped theory signifies that return variance during lunch break is lower than all return variance during morning and afternoon trading session. If the IDX also has that kind of return variance movement, it can be concluded that information dissemination during trading is correct and valid (Amihud & Mendelson, 1991; Ito & Lin, 1992). The reasons that can be presented are the pressure of morning trading sessions as a result of private information accepted before by investors. The trading pressure also drives the high return volatility during morning trading session (Ito, Lyons & Melvin, 1998).

This research examines return volatility which has phenomenon in U-Shaped form that is empirically truely and correctly occurs in IDX. This examination means that private information is proven undeniable in IDX which means a denial to the trading system based on public understanding that the trading is completely based on a set of public information. Using equivalent statement, this research examines the similarity or dissimilarity of distributive structure of return during some intervals within one day. This phenomenon becomes extremely important due to various condition of stock market, especially emerging stock market compared to advanced stock market. This research is useful for investors and potential investors to analyze current and future investment and investment decision. The acquired information is in form of stock price variability behavior during trading periods in IDX related to timing of sell-buy strategy. Another benefit of this research is return information reliability during trading period in relation with the timing of investment decision taken by the investors and potential investors.

The remaining research discussion is set as follows. Section 2 **discusses the literature reviews and hypothesis development. The developed hypothesis**

consists of main hypothesis which is re-examined using other sensitivity tests. Section 3 **discusses research methods used to examine all hypotheses.** Section 4 **discusses result and finding of this study. The last,** Section 5 **discusses conclusion inferred from the result and finding.**

2. Literature Reviews and Hypotheses Development
Information, Volatility and Trading Period

Stock price volatility is begun with investors' belief revision (Barron, 1995). The revaluation process is conducted by estimating expected return used to determine stock intrinsic value. The revaluation uses the latest data. The acquired result is compared to current price to evaluate stock price fairness. The evaluation of stock value fairness is used to decide buy-sell strategies. At this condition, there are two sides that have contradictive objectives, namely the stock buyers who expect price increase after selling, and the stock sellers who expect the price decrease. These contradictive objectives cause stock price volatility. Each time the price is set, and then during the same time the balance of stock supply and demand is set. The rate of stock price volatility is comparable to the fluctuation of stock intrinsic value, and information that arrives to investors highly influences stock price re-evaluation (Berry & Howe, 1986). Therefore, the process of stock price volatility is inseparable with the arrival of new information to investors.

Fama (1970; 1991) stated that stock price reflects all available information, including previous price, public information and private information. Private information is rarely occurred and only affects the price through trading by informed investors, which usually do trading based on investor's information for more than one day (Fama, 1991). Public information is information recognized at the same time it affect the price, before the investors are able to use it as trading decision strategy (French & Roll, 1986, Berry & Howe, 1994). Public information is presented for all investors, but evaluated differently by investors who have different beliefs (Barron, 1995, Odean, 1998). Informed and uninformed investors only do trading when new information available, such as future cash flows or other variables such as wealth, preferences, and investment opportunities. The investor's reaction against information occurs when the information arrives. The reaction causes price change that reflects the expected risks and investors acquirement (Berry & Howe, 1994).

Nofsinger (2001) supports stock return volatility pattern by examining the trading behavior of institutional and individual investors after the firm specific information and macroeconomics announcement published by the Wall Street Journal. The investors tend to pay attention to the published firm specific information especially about earnings and dividend. Institutional and individual investors buy after good economics news and sell after bad economics news. This shows that public information and macroeconomics announcement published by the Wall Street Journal highly affecting stock price volatility.

Frino & Hill (2001) stated that stock price behavior is highly affected by public information announcement in Sydney Future Exchange (SFE). Balduzzi, Elton & Green (2001) stated that the effect of most public information tends to be brief within less then 30 minutes. The analysis of price volatility, trading volume and bid-ask spreads indicates that adjustment against new information occurs very quickly, within 240 seconds the effect of new announcement is detectable. The analysis of bid-ask spreads effect also occurs within two minutes before public information and 30 minutes after the public information is published. The increase of bid-ask spreads is closely related to price volatility, which implies that market responds against public information.

Pritamani & Singal (2001) examined public information arrivals which are proxies by volume increase and price change. The results show abnormal return which becomes

greater. If the information is related to the earnings or in accordance with the analysts recommendation, abnormal return during 20 days becomes greater in range of 3,00%-4,00% for good news, and the lowest of -2,25% for bad news. Grundy & Kim (2002) stated that rank of information heterogeneity affect the increase of price variability equal to 20%-46% compared to the economics information homogeneity. This price variability means that private information positively contribute to price variability compared to public information. Suhaibani & Kryzanowski (2000) examined the information contents of new bids in Saudi Stock Market (SSM). The new bids which are greater and more aggressive are caused by information arrivals. The relative measurement of bids information implies that private information is dominant factors in stock trading decisions. Therefore, private information also affects price volatility.

Bery & Howe (1994) stated that investor's reaction against new information arrival is reflected in stock price change which indicates expected risks and acquired return. Public information is responded longer in overnight periods than morning and afternoon trading session. Therefore, return volatility is hypothesized higher during nontrading period than during trading periods. Inversely, Amihud & Mendelson (1991) and Huang, Liu, & Fu (2000) proved empirically that return volatility is higher during trading periods caused by private information arrival. Private information is published during trading periods by the informed traders, and private information is hypothesized that return during trading periods is higher than during nontrading periods.

A.

B. Examination Stage and Hypothesis

C. This study focuses on examining the existence of private information based on U-Shaped curve formula. Until recently, this formula is trading model which believe to private information arrival. Essentially, this formula explain corrected price variance during the early morning trading session (Wood, McInish & Ord, 1985; Harris, 1986; Andersen & Bollerslev, 1997; Admati & Pfleiderer, 1988; Foster & Vismanathan, 1990; Slezak, 1994). Private information refers to information that fill two criteria, namely not in form of publicly known and always related to price (Ito & Lin, 1992; Ito, Lyons & Melvin, 1998). Meanwhile, French & Roll (1986) define that private information is correctly identifiable because it is related to price momentarily or permanently. This study defines and emphasizes that private information is related to price, so that temporary and permanent impacts are still qualified as private information.

D. First stage, this study examines private information arrival based on theory shown by French & Roll (1986) and Ito, Lyons & Melvin (1998) who examined by focusing on the lowest line in U-Shaped curve. This examination is none other than lunch break. This examination uses lunch break return volatility by comparing closing return variance and opening return variance which must greater than one. Inversely, if the comparison value is equal to one, this can be considered as public information arrival, which means that return variance does not change from opening price at morning trading session until closing price at lunch break session. Therefore, private information arrival can be hypothesized as follows.

E.

F. H1**: Lunch break return volatility in IDX is caused by private information arrivals.**

G.

H. Test: $\dfrac{V_L^O}{V_L^C} > 1$

I.

J. where, V_L^C and V_L^O are closing and opening lunch break return variance. Notation: C (*close*), O (*open*) and L (*lunch*).

Second stage, this study analyse the differentiated private information arrival by examination of return volatility change during morning and afternoon trading session. Specifically, from private information theory, this study predicts the behavior of intraday return volatility which respond to opening price at morning trading session. By ignoring pricing error due to the inability of pricing error model to predict return variance, predicted return volatility change is able to confirm private information arrivals.

The examination in this second stage is conducted by assigning model exposed by Admati & Pfleiderer (1988). The research suggests that if a number of private information did not change while the trading drives the change, private information should not cause price change whose return is not distributed during morning trading session until afternoon. In fact, private information always drives price change which ends up in return distibution all day long. Therefore, this study deduces that return distribution occurs due to private information captured during trading.

K. H2: **Private information arrival is revealed during trading session marked by the decrease of lunch break return volatility (bottom line of U-Shaped curve)**

L. Test: $\dfrac{V_L^C}{V_M^C} < \dfrac{V_L^O}{V_M^O}$ **and** $\dfrac{V_L^C}{V_A^C} < \dfrac{V_L^O}{V_A^O}$

M.

N. **With additional notes from previous test, V_M^O and V_M^C are return variance during the opening and closing of morning trading session, and V_A^O and V_A^C are return variance during the opening and closing of afternoon trading session, where M (*morning*), and A (*afternoon*).**

O. **The prediction of private information arrival can be done by cutting off the trading during morning trading session for the first four hours. In other words, the trading is limited until lunch break. This cutting off is based on logical framework recommended by Ito, Lyons & Melvin (1998). This research suggested that −if not limited during lunch break− bottom line of U-Shaped curve flattens, it means that U-Shaped during one full day is not confirmed (Slezak, 1994; Hong & Wang, 1997). U-Shaped framework in morning trading session cutting off can be hypothesized as follows.**

P. H3: **The private information arrival is uncovered during morning trading session marked by increasing return variance during early morning trading session −limited until lunch break session− that is able to form U-Shaped curve during one full day**

Q. Test: $\dfrac{V_{MM}^C}{V_{EM}^C} < 1$ **and** $\dfrac{V_{LM}^C}{V_{MM}^C} > 1$ **and** $\dfrac{V_{LM}^O}{V_{MM}^O} \leq 1$

R.

S. With additional notes from previous tests, V_{EM}^{O}, V_{EM}^{C}, V_{MM}^{O}, V_{MM}^{C}, V_{LM}^{O} and V_{LM}^{C} are return variance during the opening or closing price at early, mid, and late morning trading session. Additional notes: EM (*early morning*), MM (*mid morning*), and LM (*late morning*).

The examination of private information arrival continues by referring research concepts exposed by Kyle (1995). This research stated that private information is not related to price in long term. On the contrary, private information should be related only to price in short term because informed traders always choose to do trading as long as the information is reflected by the price (Ito, Lyons & Melvin, 1998). Return volatility during short term is suspected whether the opening return variance is higher than closing return variance. It means that opening return variance during morning trading session affects the return variance during all morning trading session. Moreover, opening return variance during afternoon trading session should also be determined by return variance during previous morning trading session, because traders are motivated not to delay their transaction which enlarges return variance during morning trading session. Such characteristic refers to private information model (Foster & Viswanathan, 1990). This comparative condition can be used to develop hypothesis that private information always occurs during short term as follows.

T. H4**: The private information arrival is revealed during trading session in short term when opening return variance ratio is greater than closing return variance ratio outside lunch break (forming the descending line of U-Shaped curve)**

U. Test**:** $$\dfrac{\left(\dfrac{V_{M}^{O}}{V_{A}^{O}}\right)}{\left(\dfrac{V_{M}^{C}}{V_{A}^{C}}\right)} > 1$$

V.

W. With additional notes from previous test, V_{M}^{C}, V_{A}^{C}, V_{M}^{O} and V_{A}^{O} are return variance during opening or closing morning trading session and afternoon trading session.

3. Research Method

X. The sample in this research is companies listed in LQ45 index during either first or second semester of 2006-2007. LQ45 selection is based on reasons that companies listed in LQ45 have high liquidity, so this study are able to minimize sleeping stocks during the trading day. The sleeping stock can affect internal and conclusion validity of this study. This sample selection method is used because IDX is thin market marked by lots of sleeping stocks.

Y.

Z. *Return*

AA. Opening and closing price for return each 30 minutes interval lay in trading day which acquired from intraday data. Return is calculated by natural logarithm of relative price $R_{i,30',(t)} = \ln(P_{i,30',(t)}/P_{i,30'-1,(t)})$ where *i* is firm and *t* is day for each firm. To calculate 30 minutes interval return,

companies' trading data is divided into 12 intervals, and the formulation is as follows.

Return interval 30'number -01	: $R_{i,16.00(t-1)-09.30(t)} = \ln(P_{i,09.30(t)}/P_{i,16.00(t-1)})$
Return interval 30'number -02	: $R_{i,09.30(t)-10.00(t)} = \ln(P_{i,10.00(t)}/P_{i,09.30(t)})$
Return interval 30' number -03	: $R_{i,10.00(t)-10.30(t)} = \ln(P_{i,10.30(t)}/P_{i,10.00(t)})$
Return interval 30' number -04	: $R_{i,10.30(t)-11.00(t)} = \ln(P_{i,11.00(t)}/P_{i,10.30(t)})$
Return interval 30' number -05	: $R_{i,11.30(t)-11.00(t)} = \ln(P_{i,11.30(t)}/P_{i,11.00(t)})$
Return interval 30' number -06	: $R_{i,12.00(t)-11.30(t)} = \ln(P_{i,12.00(t)}/P_{i,11.30(t)})$
Return interval 30' number -07	: $R_{i,13.30(t)-13.00(t)} = \ln(P_{i,13.30(t)}/P_{i,13.00(t)})$
Return interval 30' number -08	: $R_{i,14.00(t)-13.30(t)} = \ln(P_{i,14.00(t)}/P_{i,13.30(t)})$
Return interval 30' number -09	: $R_{i,14.30(t)-14.00(t)} = \ln(P_{i,14.30(t)}/P_{i,14.00(t)})$
Return interval 30' number -10	: $R_{i,15.00(t)-14.30(t)} = \ln(P_{i,15.00(t)}/P_{i,14.30(t)})$
Return interval 30' number -11	: $R_{i,15.30(t)-15.00(t)} = \ln(P_{i,15.30(t)}/P_{i,15.00(t)})$
Return interval 30' number -12	: $R_{i,16.00(t)-15.30(t)} = \ln(P_{i,16.00(t)}/P_{i,15.30(t)})$

Trading Session and Return

Trading session is not equal during each day. Trading is opened at 09.00 every day, but the first session is closed at 12.00 on Monday until Thursday, while on Friday the first session is closed at 11.30. the second session is opened at 13.30 on Monday until Thursday, while on Friday the second session is opened at 14.00. the second session is closed at 16.00 every day. **Picture 1** shows trading day and trading period along with their relation with hypotheses examination in this research.

Insert Picture 1 about here

Data Analysis

Data analysis was conducted analysis in the following procedural steps:

1. From intra-day data, 12 series of price was obtained that is price within 30 minutes interval. This 30 minutes interval price was used to calculate return.
2. Calculating return by $R_{i,30',(t)} = \ln(P_{i,30',(t)}/P_{i,30'-1,(t)})$, which is return within minute interval from the first until twelfth. Opening return was calculated by $\ln(P_{i,09.30(t)}/P_{i,16.00(t-1)})$
3. Forming 12 series of 30 minutes interval return from Monday until Friday to determine the sensitivity rate against noise and overreaction. The analysis in this examination is only focused to differentiate the return in one 30 minutes interval from other returns of 30 minutes interval.
4. Eliminating the days around dividend announcement under the reason to eliminate high price fluctuation (H_{-3} and H_{+3}), and to make adjustment against stock dividend, stock split, bonus share and stock reserve split.
5. Identifying points related to **OM:** open morning**; OEM:** open early morning; **CEM:** close early morning; **OMM:** open mid morning; **CMM:** close mid morning; **OLM:** open late morning; **CM:** close morning; **CLM:** close late morning; **OL:** open lunch; **CL:** close lunch; **OA:** open afternoon; and **CA:** close afternoon.
6. Calculating V_L^C, V_L^O, V_M^C, V_A^O, V_{EM}^O, V_{EM}^C, V_{MM}^O, V_{MM}^C, V_{LM}^O, V_{LM}^C, V_M^C, V_A^C, V_M^O and V_A^O, which consecutively show variance during opening (O: *open*), closing (C: *close*), lunch break (L: *lunch*), morning trading session (M: *morning*), afternoon trading session (A: *afternoon*), and the two digits letter begining with E, M dan L which represent early morning trading session (E: *early*), mid morning trading session (M: *mid*) and late morning trading session (L: *late*).
7. Examining all hypotheses according to applicable ratio

4. Results and Findings

The first part of this section examines the first stage to prove the non existence of return variance during lunch break. Later, this research examines the second stage to prove the private information arrival along with its effect duration within relatively short term. The descriptive statistics begins firstly in this section.

Descriptive Statistics

The descriptive statistics shows highly varied 30 minutes interval data during 2006. Inference that can be derived from **Table 1** is the magnitude of mean of return 30 minutes interval with the lowest number during the period from previous day closing until the following 09.30 at -0,00093. This lowest mean is at the beginning of 30 minutes interval. Meanwhile, the highest mean of return of 30 minutes interval during the period of 09.30-10.00 is 0,0005 and during the period of 15.30-16.00 is 0,00424.

Inference derived from these mean figures is that the highest mean is within the earliest 30 minutes interval during early morning trading session and within lately trading day. This condition serves as the evidence that the return is surging compared to the previous 30 minutes interval. Meanwhile, the number of observations for the first 30 minutes interval is 10.845 and from this sum, only 9.956 are usable or 889 are excluded. This exclusion is caused by lack of transaction during this interval causing no price differences or no return. This explanation is applicable for the rest discussion.

Insert Table 1 about here

The standard deviation of each 30 minutes interval varies in relatively equal number. For 30 minutes interval during period 15.30-16.00 is 0,00708. The minimum value, maximum value, and skewness value are presented following the standard deviation column. For instance, minimum value for the last 30 minutes interval during trading day (return of 15.30-16.00) is -0,03, the maximum value is 0,04 and the range between minimum value and maximum value is 0,07. The high return during 09.30-10.00 and 15.30-16.00 along with the low return and the effect of last trading day becomes clearly observed in graphically presentation as presented in **Figure 2**.

Insert Figure 2 about here

First Stage Examination Result

The first hypothesis states that return volatility during lunch break at IDX is caused by private information arrival. This hypothesis can also be interpreted that return variance during opening of lunch break session is greater than return variance during the closing of lunch break session. The examination in this stage used the whole sample using the period of three first months within year of observation, period of six cumulative months from the first period, period of nine cumulative months from both previous periods, and period of twelve cumulative months from three previous periods. The examination result shows that ratio between return variance of the opening of lunch break session and return variance of the closing of lunch break session is greater than one. The examination result for all samples is presented in **Table 2**.

Insert Table 2 about here

      Inference derived from Table 2 is as follows. All ratios between return variance during lunch break opening and return variance during lunch break closing are greater than one. These ratios are in detail within a range between 2.7 and 3.3. These ratios tested by mean comparison tests show statistically significant result, with t-value (sig.) equals to 14.7710 (0.000). Therefore, we conclude that opening return variance during lunch break compared to closing return variance during lunch break is not caused by public information arrival but private information arrival instead. In the beginning evidence, this research supports the concept exposed by French & Roll (1986) and Ito, Lyons & Melvin (1998).

Second Stage Examination Result

The second stage examination begins with hypothesis H2 examination. This second stage examination enhances the proofing of private information arrival at IDX. In other words, this examination also deepens to prove U-Shaped curve formulation or also shows return volatility within one day. This second stage examination is also conducted using all sample with the period of the first three months with the observation year, period of six cumulative month from previous period, period of nine month from both previous periods, and period of twelve months from all three previous periods. **Table 3** shows in detail the examination result from all samples.

Insert Table 3 about here

      Inference derived from Table 3 shows that opening return variances during morning and afternoon trading session are greater than the closing return variances during afternoon trading session or trading around lunch break session. The figures presented in Table 3 are results of following calculation. Opening return variance during lunch break session is divided by opening return variance during the following morning trading session. The result is then divided by the ratio between closing return variance during lunch break and closing return variance during morning session. Similarly, this formula is also applicable for the third column. The result shows that the ratio is greater than one. This means that the opening return variance during morning session is the greatest number which affects all return variances during morning trading session. This result can also be interpreted as that return variance during lunch break session is smaller than opening return variance during morning session and closing return variance during afternoon trading session.

      All ratios are greater than one, which in details are in a range between 1.13 until 17.57, except for the third row that is 0.97. These ratios examined by one sample mean comparison test show statistically insignificant difference with t-value (sig.) that equals to 1.660 (0.195). However, when examined by one sample mean comparison test using one lag show statistically significant with t-value (sig.) that equals to 2.593 (0.085). The conclusion is that hypothesis **H2** could be supported. This result indicates existence of opening return variance during lunch break compared to opening return variance during morning trading session due to private information arrival. Therefore, closing return variance during afternoon trading session is greater than opening and closing return variance during lunch break, and opening return variance during afternoon trading session. With the confirmation that all ratios are greater than one, this concludes that bottom line in U-Shaped curve is the lowest return variance compared to all return

variance within full day. In the beginning evidence, this research, once again, supports the concept recommended by French & Roll (1986) and Ito, Lyons & Melvin (1998).

The second stage examination is contiued with hypothesis H3 examination. Hypothesis H3 states that private information arrival is revealed during morning trading session marked by return variance during early morning trading session which should be greater than mid and late morning trading session. The test is limited until return variance during lunch break in order to be able to form U-Shaped curve. This hypothesis has simple reason that if U-Shaped curve is confirmed only during morning trading session, U-Shaped curve within one day can not be confirmed. Therefore, the confirmation of U-Shaped during morning trading session denies the private information arrival whose opening return variance during early morning session does not affect return variance during within one day. Related to this reason, this study does not wish to prove that hypothesis H3 is supported. The detailed examination result of hypothesis H3 is presented in **Table 4** as follows.

\-
Insert Table 4 about here
\-

The examination result presented in Table 4 confirms that closing return variance during mid morning trading session is greater than closing return variance during early morning trading session. Therefore, the verification in second column of Table 4 shows opposite from that was hypothesized, that ratio of closing return variances should be less than one, but it is greater than one instead. Furthermore, the ratio, which is inversed, when examined by one sample mean comparison test using one lag results is statistically significant difference, with t-value (sig.) that equals to 4,540 (0,020). The opposite result from this examination that was hypothesized is also shown in third column. It means that ratio of closing return variances that was supposed to be greater than one but it is less than one instead. Furthermore, the third column shows opposite figure of the ratio from that was hypothesized and also statistically insignificant.

The examination result shown in the third column of Table 4 signifies that during morning trading session, the U-Shaped curve cannot be confirmed. Therefore, hypothesis H3 is not supported. This should serve as proof that U-Shaped curve should not be proved within one day. Therefore, this study concludes that opening return variance is still the biggest one which affect all variance within one full day. The temporary conclusion is that this result strengthens H1 and H2 examinations. It means that return variance at IDX is caused by private information arrival or supporting to the validity of U-Shaped curve formulation within full day period (French & Roll, 1986 and Ito, Lyons & Melvin, 1998).

The second stage is sharpened by hypothesis H4 examination. Hypothesis H4 states that private information arrival is revealed during short term trading when ratio of opening return variance is greater than ratio of closing return variance at the outside of lunch break or when bottom line of U-Shaped curve is deepened. Another reading method to this hypothesis is that opening return variance during morning trading session is compared to opening return variance during afternoon trading session then divided by ratio between closing return variance during morning trading session and closing return variance during lunch break. In addition, this ratio should be greater than one. The examination result is presented in Table 5 as follows.

\-
Insert Table 5 about here
\-

The result presented in Table 5 signifies that hypothesis H4 is supported. It means that all return variance ratios are greater than one, with the lowest ratio is 1.794 and the highest one is 10.3987. The ratios when examined by one sample mean comparison test result statistically significant difference with t-value (sig.) that equals to 2.810 (0.067). The conclusion from this examination is the confirmation of private information arrival which always related to price and the arrival occurs within one trading day or does not have permanent influence against stock price (French & Roll, 1986; Foster & Viswanathan, 1990; Kyle, 1995; and Ito, Lyons & Melvin, 1998). Such examination result can also be interpreted as in supporting with hypotheses H1 and H2.

Sensitivity tests by firm size
A sensitivity test by firm size is served to control the consistency of hypothesis by hypothesis examination that has been completed before. Hypothesis H1 is re-examined by firm size quintiles. This research divides firm size into five categories from the smallest to the biggest ones. Furthermore, the consistency of hypothesis examination for each firm size category is expected to gain consistent results. The detailed examination result is presented in Table 6 as follows.

Insert Table 6 about here

Table 6 shows that ratio between opening return variance during lunch break and closing return variance during lunch break is greater than one for almost all firm size, except the smallest one. The examination result using one sample mean comparison test with one lag shows that firm size that is not included in the smallest ones (B group or above) have statistically significant difference, with t-values (sig.) that consequtively equal to 3.038 (0.056), 5.905 (0.010), 2.974 (0.059), and 4.5 (0.020). Hypothesis H1 is once again supported which means that opening return variance during lunch break compared to closing return variance during lunch break is not caused by public information arrival, but private information arrival instead (French & Roll, 1986 and Ito, Lyons & Melvin, 1998). Therefore, medium to big firm size tend to capture private information at IDX.

The hypothesis H2 examination strengthen the confirmation of U-Shaped curve, which means that private information arrival is undeniable if the opening return variance during early morning trading session compared to closing return variance during lunch break or return variance during around lunch break is greater than one. The examination shows consistent result with previous hypothesis H2 examination, that is return variance during lunch break must be less than opening return variance during morning trading session and closing return variance during afternoon trading session. The detailed result is presented in Table 7 as follows.

The result presented in Table 7 shows that the first ratio is proven greater than one for medium firm size. Examination using one sample mean comparison test with one lag results statistically significant difference with t-value (sig.) that equals to 7.500 (0.005). Meanwhile, the ratio of second return variance is proven greater than one from the smallest firm size until the biggest firm size. The statistics examination show t-value with significance level of 5% and 10%. Therefore, this study concludes to confirm that all ratios are greater than one, then the bottom line of U-Shaped curve is the lowest return variance compared to all return variances within one day.

Insert Table 7 about here

Hypothesis H3 states that if U-Shaped curve is proven only during morning trading session, U-Shaped curve within one day cannot be proved. The examination results of firm size quintiles are presented in Table 8.

Insert Table 8 about here

Table 8 shows a notably interesting result. Except medium firm size (column C), all other three ratios examined for hypothesis H3 are supported. As previously explained, this study has motivation not to support hypothesis H3. The results show that for all firm size, except medium firm size, the first return variance ratio does not support hypothesis H3. Similarly, for all firm size, except medium firm size, the second return variance ratio is proven not to support with hypothesis H3. Therefore, this research concludes that hypotheses H1 and H2 is once again supported. This means that return variance at IDX is caused by private information arrival or in supporting to the validity of U-Shaped curve formulation for every trading day in the stock market.

The re-enhancement by hypothesis H4 examination shows that private information arrival is revealed during short term trading if ratio of opening return variance is less then ratio of closing return variance outside lunch break or if the descending line of U-Shaped curve is formed. The result is presented in detail at Table 9 as follows.

Insert Table 9 about here

The result presented at Table 9 signifies that hypothesis H4 is supported. It means that all examined return variance ratios are greater than one. These ratios when examined by one sample mean comparison test with one lag result is statistically significant difference, with t-values (sig.) that equal to 4.225 (0.024) for smallest firm size (column B), 2.427 (0.094) for medium firm size, and 4.061 (0.027) for the biggest firm size. This examination result is once again in supporting to hypotheses H1 and H2. This study concludes the comfirmation of private information arrival which is always related to stock price within one day or does not influence stock price permanently (French & Roll, 1986; Foster & Viswanathan, 1990; Kyle, 1995; and Ito, Lyons & Melvin, 1998).

Sensitivity tests by trading volume
Similar to sensitivity tests by firm size reasoning, sensitivity tests by trading volume is aimed to ensure the consistent results of this research hypothesis. The examination is conducted by dividing the sample into trading volume quintiles, which are, in ascending order, the smallest, B, C, D, and the biggest. The order of subsection analysis and discussion are similar to the previous discussion of sensitivity tests by firm size. The detailed analysis result is presented in following tables.

Table 10 for hypothesis H1, Table 11 for hypothesis H2, Table 12 for hypothesis H3, and Table 13 for hypothesis H4 examinations show result which do not too far in comparison with the result of firm size sensitivity tests. Considering that on sensitivity tests by firm size, hypothesis H1 is supported, hypothesis H2 is supported, hypothesis H3 is not supported, and hypothesis H4 is supported. Therefore, this research concludes that results of trading volume examination are consistent with the previous results. Therefore, this research concludes the same as before.

645

Insert Table 10 about here

Insert Table 11 about here

The private information arrival is undeniable because opening return variance during early morning session compared to closing return variance during lunch break session or return variance around lunch break is greater than one. In other words, return variance during lunch break session must be smaller than opening return variance during morning session and closing return variance during afternoon session. This finding is consistent and in supporting to hypothesis H1. Therefore, the bottom line of U-Shaped curve is the return variance during lunch break which is the smallest variance compared to all return variance within one day. This finding is also in supporting to hypothesis H2. Furthermore, hypothesis H3 examination also confirms that U-Shaped curve is not proven during morning session of trading day. This means that U-Shaped curve is a function of return variance in full day period. The last one, hypothesis H4 examination shows that private information arrival is always related to the stock price and its arrival occurs within one trading day or does not have permanent effect on stock price. The overall results of hypothesis by hypothesis examination on trading volume sensitivity tests conclude that private information occured and is proven valid in IDX.

Insert Table 12 about here

Insert Table 13 about here

Sensitivity tests by bid-ask spreads
This examination has equal reason which is in accordance with both firm size and trading volume examinations. Sensitivity tests by bid-ask spreads is conducted to examine hypotheses test consistency. This study divided sample into bid-ask spreads quintiles, which are, in ascending order, the smallest, B, C, D, and the biggest. From Table 14 until Table 17 show similar results compared to the previous examination by both firm size and trading volume. All examinations confirm that private information arrival is proven valid in IDX. This is marked by the opening return variance during early morning session compared to closing return variance during lunch break or return variance around lunch break which is greater than one. This finding is consitent and in supporting to hypothesis H1. Therefore, the bottom line of U-Shaped curve is return variance during lunch break which is the smallest variance compared to all return variance within one day. This finding supports to hypothesis H2. Furthermore, hypothesis H3 examination also confirms that U-Shaped curve did not exist during morning trading session. This means that U-Shaped curve is a function of return variance in full day period. The last one, hypothesis H4 examination, shows that private information arrival is always related to stock price and its arrival occurs within one trading day or does not have permanent effect on stock price. The detailed results of hypothesis by hypothesis examinations are presented in the following consecutive tables.

Insert Table 14 about here

Insert Table 15 about here

Insert Table 16 about here

Insert Table 17 about here

Findings and Consequences

BB.   This study, after all hypotheses are examined and their sensitivity are reexamined using firm size, trading volume, and bid-ask spreads sensitivity tests, finds evidence that existence and occurence of U-Shaped curve is proven valid. This means that opening return variance during early trading period is the highest return variance compared to the return variance around lunch break. With the sign of the highest return variance during early trading period, this study concludes that private information arrives at every morning trading session in IDX. This confirmation is also supported by the existence and occurence of high closing return variance around late afternoon trading session. Therefore, U-Shaped curve formula is closing to the complete form, so that it can be concluded that private information always occurs.

CC.   The existence and occurrence of private information arrival is also sharpened by the result of examination of U-Shaped curve which does not occur only during morning trading session. The point is, with all confirmed results of this U-Shaped form, return formulation in U-Shaped curve occurs within sub period of day. This study later found evidence sharpening that private information is revealed impermanent on the IDX' stock price or in short term. This study finds that private information always related to stock price during every stock trading in IDX.

DD.   With the confirmation of U-Shaped curve formula at IDX, this study formulates a trading strategy that can be applied by investors. The investors at IDX could do trading if only they have information, refers to informed investors. This strategy must also be complemented not just with information, but also with strict observed time when return variance is high. This high return variance occurs during early morning trading session and during late afternoon trading session. The investors' prudential behavior is necessary to observe high return variance during early morning trading session and late afternoon trading session along with specific information acquired which is not well known publicly among other investors.

EE.   The timing of expected return gains becomes the second strategy found in this study. The investors who wish to acquire high return should trade during period when the return variance is high, that is during early morning trading session or during late afternoon trading session. However, during all this time, the investors may also experience great losses. Meanwhile, if the investors wish for certain returns but in small number, the investors should trade during around before and after lunch break. The reason is, during around this period, it is proven that lunch break return variance is the lowest compared to other return variance within one day period. This can also be inferred that the period having

the highest return variance refers to the high risk period, whereas the period having low return variance refers to low risk period. The prudential behavior for investors trading during high return variance is absolutely necessary.

FF.　　　　　Sell-buy strategy is the third findings in this study. By maintaining the concept of informed investors, buy strategy can be applied during around lunch break, and sell strategy can be applied during late afternoon trading session or during late morning trading session on the next day. This concept also formulates that buy strategy to hold stock inventory is recommended during period having the lowest return variance. Inversely, sell strategy is recommended to be applied during period having high return variance. This means that investors should wait during early morning trading session on the next day, to see whether there is new information arrival or not. The reasons that support this sell-buy strategy is shown that stock mispricing only occurs during period having high return variance and it is not likely to occur during period having low return variance. The last attention to these all findings is to be considered that private information arrival is not related to stock price permanently, or the relationship between private information and stock price only occurs within period that is not longer than one day.

GG.

5. Conclusion and Limitations

EE.　　This study is able to confirm the existence and occurence of return formulation at IDX in form of U-Shaped curve, as the return variance formulation at other countries stock market. Basically, this study concludes the research findings as follows. *First*, the existence and occurence of private information at IDX is proven valid. *Second*, return variance during morning trading session is the highest value which affect all return variance during morning and afternoon trading sessions. *Third*, U-Shaped curve during morning trading session does not confirmly occur and exist, so that return variance during morning trading session affects all return variance within one day of trading. *Fourth*, the effect of private information arrival occurs within short term.

FF.　　　　　All four conclusions have impacts against trading strategy for investors at IDX. The best strategy that should be applied is: (1) the investors do trading if only they have information, (2) investors who wish for high returns should trade during period having high return variance, that is during early morning trading session or during late afternoon trading session, (3) by maintaining the concept of informed investors, buy strategy may be applied during around lunch break session, and sell strategy may be applied during late afternoon trading session or during early morning trading session on the next day, and (4) investors should keep in their mind that private information arrival does not related to price permanently, or the relationship between private information arrival and stock price only occurs within period that is not longer than one day.

GG.　　　　This study has limitations that may decrease conclusion validity of this study. These limitations are as follow. *First*, this research only used 30 minutes interval data, whereas the price high price instability may occur within 30 minutes. This price variability is not captured within this study. *Second*, this study used sensitivity tests on firm size, trading volume and bid-ask spreads. Further study can be designed by applying trading day and market-up or -down condition. *Third*, this research used all stock within LQ45 list index, so that it only describes the high frequency traded stock. *The Last*, this study assumes and this assumption serves as its limitation. This assumption is that bid-ask spreads is not

based on the information asymmetry concept but transitory component concept instead. The concept of transitory component calculates spread value based on inventory cost and its completion cos**t.**

2.5 Corporate Governance

CORPORATE GOVERNANCE AND
PERFORMANCE OF THE LISTED COMPANIES IN TSE

Vida Mojtahedzadeh, Al-Zahra University
Seyed Hossein Alavi Tabari, Al-Zahra University

Abstract

This paper examines the relationship between corporate governance & performance of the listed companies in Tehran Stock Exchange (TSE). Reviewing the literature, four criteria were selected to assess corporate governance, including; Board Size, Proportion of External Members of the Board, Proportion of Common Stocks owned by Major Shareholders & Proportion of Common Stocks owned by Individual Shareholders(Free Float shares) and two criteria to measure performance, including Return on Assets (ROA) and Return on Equity (ROE) . The statistical sample consisted of 71 firms chosen from companies listed in TSE during a 5-year period 2002-2006.

The hypotheses were analyzed by Panel Data regression , F and t-test. The results show that all criteria, except the Proportion of External Members of the Board (hypotheses 2), have a significant relationship with performance.

Introduction

According to the Cadbury committee(1992), some of the features of corporate governance include the presence of external members in the board of directors, separation of the chairman of the board from the CEO, presence of subsidiary board committees (i.e. auditing committee), ownership by CEOs and the proportion of ownership by major stockholders. In the report presented by this committee, it was suggested that in order to perform better, firms should follow certain rules of corporate governance. Although conformance with these rules was optional, it was expected that companies adhere to them and change their structures. Therefore, they were set as a qualification for persisting in Stock Exchange and then listed companies were obliged to

present their procedures of following that in the annual reports. Otherwise they had to disclose the reasons (Laing, Mc. Knight and Weir, 1999).

The Cadbury committee suggested the establishment of a system based on the assumption that external members of the board and subsidiary committees of the board are sensitive to corporate governance. It also accentuated the importance of independence and adequacy of external members. The proposals made by this committee, especially on the appointment of subsidiary committees, were welcomed by the companies (Conyon & Mallin, 1997).

However, very little work has been done on assessing the impact of the establishment of subsidiary committees and its quality on the performance of companies (Dalton et al., 1998).

The primary responsibility of external members is to ensure that CEOs adhere to the guidelines established, for the benefit of shareholders (Fama, 1980). These members have two main characteristics which enable them to perform their supervisory functions, first their independence (Cadbury, 1992) and second their concern for their reputation in the managerial market (Fama & Jensen, 1983).

Although external members of the board benefit from characteristics such as independence and experience, but evidence suggests that these characteristics do not have a positive impact on performance. Results obtained from certain researches suggest that the presence of independent managers may hurt firm performance. Yermack, Agrawal and Knoeber(1998) have discovered a negative relationship between the level of independence experienced by directors and performance . Bhagat and Black (1998) have also reported a similar negative relationship .

Baysinger and Hoskisson(1990); Hermalin and Weisbach (1991) believe that a relationship exists between the composition of the board of directors and firm performance (for a period of one year) . However, Baysinger and Butler (1985) have offered, with a ten year period delay, evidence on the presence of a relationship between the mentioned factors .

Based on the literature, little concurrence exists on the relationship between the number of external members and firm performance; therefore it seems that more research has to be carried out on this subject.

Where chairman of the board of directors and the CEO are the same person, supervision will encounter serious obstacles. According to Fama and Jensen(1997), if the company manager who is also the chairman of the board controls the board of directors, supervision will be very difficult . The Cadbury committee(1992) supported this and claimed that such a fact would be quite inappropriate since it would give one person too much decision making power .

However, very little evidence supports this claim. Most of the researches carried out in this regard do not indicate an adverse relationship between joining the responsibilities of the CEO and the chairman of the board with firm performance (Brichley et al.,1999; Theodorou & Vafeas, 1998; Dalton et al., 1998; Weir & Lainy, 1999).

Dahya et al(1996) observed in a small population of British companies that the stock market shows a significant positive reaction to the separation of the chairman from the CEO. Moreover companies that did not have such a situation presented a weaker performance as compared to the years when the two responsibilities were carried out by the same person. They have, however, carried out their research during U.K.'s period of economic crisis when other factors could have possibly affected performance as well. In the proposals presented by the Cadbury committee, however, only little evidence is present to indicate that the segregation of these two responsibilities hurts performance.

The other proposal offered by the committee is to establish a subsidiary committee of the board of directors (auditing committee) in all listed companies. The responsibilities of the auditing committee include signing agreements with independent auditors, reviewing the financial statements of a company and to make suggestions based on the findings of internal auditors. According to the Cadbury committee, the auditing committee should have a minimum of three members solely from external CEOs, which means that the majority of the members should be independent.

There are few researches on the impact of the auditing committee on performance. Wild(1994) discovered that the market reacts favorably to income reports received subsequent to the formation of the auditing committee , while Klein(1998) observed that the presence of an auditing committee has no impact whatsoever on market performance criteria. Results of his study indicated that variations in the composition of the auditing committee do not result in abnormal yield .

The higher the ownership of major shareholders, the higher the agency expenses due to weaker firm performance. Therefore, increasing ownership interests of major

shareholders raises the level of motivation for supervision. Evidence approves the presence of a relationship between increasing the number of individual shareholders with better performance (Schleifer & Vishny, 1986; Leahy & Leech, 1999).

If the internal strategies of a firm are weak, the market can control it through its governance system. Inappropriate strategies will lead the company to a weak performance (Fama, 1980).

In the present research, the relationship between some of the corporate governance factors including the structure of the board of directors, proportion of ownership by major shareholders and the amount of free float shares, with the performance of listed companies in TSE was studied.

History of Research

Sarkar(2008) studied the criteria used in determining incentives and salaries for CEOs with a highlight on the relationship between salaries and performance. The sample included 500 companies studied for the four quarters of the year 2003. The performance criteria included firm's book to market value, Tobin's Q, asset return and added value of assets.

Results indicated that with regards to the composition of the board of directors, external members do not play a strong supervisory role. When the company has no external members, the level of salary paid to managers was higher. Although, in companies lacking external members, a higher coordination was observed between CEOs and shareholders.

Krivogorski (2007) studied the relationship between ownership and the structure of the board of directors with performance of the European continent. The research sample consisted of 87 European companies between the years 2000-2001. Criteria selected for assessing performance included asset return, return on capital and book to market value of the company. The first couple of criteria are accounting ratios and the last one is a market ratio.

Independent variables have been classified into two groups namely, indices to measure the board composition and empirical indices to calculate ownership concentration. Indices used for the composition of the board of directors include the proportion of internal members, proportion of external members within the board of directors, proportion of highly educated CEOs within the board and separation of the chairman and

the CEO, and empirical indices to measure ownership concentration include the proportion of inside ownership, proportion of family ownership, proportion of inherent ownership and the proportion of ownership by block shareholders. Control variables are company age (number of years that company's stocks have been exchanged within markets), operational leverage, company size and growth. To test the hypotheses, Pierson's correlation was used.

Results reflected a positive relationship between the level of ownership by block and inherent shareholders with the company's profitability ratios, and to the same extent a positive relationship existed between number of external members within the board with profitability ratios. However, no relationship has been observed in European corporations between internal members or internal ownership with profitability.

Shijun(2007) investigated the relationship between board size and variability of firm performance. The research sample consisted of 1252 companies studied between 1996 and 2004. The study used stock returns to measure stock performance, annual return on assets to measure accounting performance, Tobin's Q for measuring corporate performance. The board size was defined as the number of CEOs present within the board and the proportion of independent CEOs was used to measure the composition 0f the board.

The study was performed not only for each company each year but also for panel data and based on Glejser tests (1969). Results indicated that a relationship exists between a large board of directors with less extraordinary items, inaccuracy of predictions and lower R&D expenses. Previous researches indicated that a large board of directors may be optimal in certain situations and that a negative relationship between the board size and corporate performance may be due to other external factors (Harris & Raviv, 2006; Raheja, 2005). Results of this research has complimented previous studies and indicated that corporate performance varies with board size .

Tang(2007) has studied 245 small companies in the United States between the year 2000 and 2004 to examine the mutual effects of corporate governance on performance.

Independent variables of the research included the following:

1- An independent board of directors (with criteria such as the right to fill in the position of CEO and the proportion of external members) each separately examined.

663

2- Ownership of the CEO

3- Incentives based on the performance of the CEO

The dependent variable of the research has been firm performance determined through Tobin's Q. The control variable's been company size (total assets) and industry type.

Results reflected a mutual and significant relationship between an independent board of directors, company leverage, ownership by the CEO and incentives based on performance. Considering the influence of corporate governance on performance, leverages reduced company value to a certain extent; while incentives paid to CEOs based on performance had a positive relationship with firm performance. Moreover, a weak relationship was observed between an independent board of directors and firm performance.

Omran(2007) studied on the effects of ownership concentration on performance in capital markets in Arabian countries. The sample consisted of 304 companies from countries such as Egypt, Jordan, Oman and Tunis between the years 2000 and 2002. The Panel regression method was used to test the hypotheses and assessment criteria involved return on assets, return on capital and Tobin's Q. In this research, ownership concentration has been defined as the percentage of stocks held by three major block investors. Block investors refer to those investors holding more than 10 percent of the company's shares. Results reflected that ownership concentration has a negative relationship with legal support and does not distinctly reflect a specific influence on the firm profitability and performance. Moreover, separation of the CEO and the chairman of the board does not have a meaningful effect on firm performance. However the presence of block investors and the separation of the CEO and the chairman does reflect a positive relationship between Tobin's Q and ownership concentration. Large companies and those that are less limited in their economic transactions report a higher profitability.

Method of Research

Research variables have been divided into two categories. The first category involves criteria for corporate governance while the second includes criteria for operational performance. There are four criteria for corporate governance, namely, "Board Size", "Proportion of External Members of the Board", "Proportion of Common Stocks owned

by Major Shareholders" and "Proportion of Common Stocks owned by Individual Shareholders(Free Float shares)" which are also independent variables in this study. Operational performance with the ROA and ROE criteria, are the dependent variables of the research.

- **Board Size:** The number of CEOs (whether externally or internally involved) that are members of the board of directors as well (Jong et al., 2002).

- **External member of the Board:** A part time member of the board of directors that do not hold an executive position within the company and do not receive monthly or annual salaries. The proportion of these members is obtained by dividing the number of external members present at the Annual General Council by the total number of members (Jong et al., 2002).

- **Major Shareholders:** Shareholders which own at least 5% of the marketable shares of the company (Jong et al., 2002; Mahavarpour, 2007).

- **Free Float Shares:** To calculate the number of free float shares, shares owned by major and inherent shareholders are deducted from the total number of shares (Abdoh Tabrizi, 2003).

Jong et al (2002), have used the following model to examine the effects of corporate governance on firm performance:

Performance = f (Corporate governance variables , Control variables)

The model used criteria such as the return on equity, Tobin's Q and return on assets for evaluating firm performance. Moreover variables such as the size of the board , proportion of external members of the board, proportion of ownership by major shareholders, proportion of ownership by individual shareholders (free float shares) and proportion of ownership by institutional shareholders were used as indices for corporate governance. Company value and leverage were the control variables of the model. The regression model was presented as follows:

Performance $_{i,t}$ = β0 + β1 BRDSIZE + β2 BRDEXT $_{i,t}$ + β3 FINAN $_{i,t}$ + β4 INDIV $_{i,t}$ + β5 INDUS $_{i,t}$ + β6 LOG(BVTA) $_{i,t}$ + β7 LEV $_{i,t}$ + € $_{i,t}$

Performance: Firm performance

BRDSIZE: Board Size

BRDEXT: proportion of external members of the board

FINAN: Proportion of ownership by major shareholders

INDIV: Proportion of ownership by individual shareholders (proportion of Free Float Shares)

INDUS: Proportion of ownership by institutional shareholders

LOG (BVTA): Logarithm of the book value of assets

LEV: Leverage

The method of research selected is based on the model presented by Jong et. al. to evaluate firm performance which would be the dependent variable in the study, two criteria were selected including the return on equity and return on assets. This has been due to the fact that the information required for the calculation of the Tobin's Q had not been available. Independent variables of the research included board size, percentage of external members of the board, proportion of ownership by major shareholders , and the proportion of ownership by individual shareholders (percentage of Free Float Shares).

Scope of Subject: The scope of the subject in this research is the effects of corporate governance on the performance of companies listed in Tehran Stock Exchange.

Scope of Research: Companies listed in Tehran Stock Exchange.

Time Scope of Research: The time scope selected for this research was a five year period between the years 2002 to 2006.

Out of the 421 companies in the primary population, 71 were selected as the final sample.

Upon collection of information, related folders were designed in the excel format and the variables calculates through SPSS and Eviews software.

In the present research, data for 71companies was collected for a period of 5 years. Therefore, it was quite possible that a correlation existed between the data and that data were not independent of each other, and subsequently data independence which was one of the regression hypotheses could not be valid. Thus the Panel Data regression model (whole-piece data) was used to estimate coefficients and to assess the model.

Considering that the normality of distribution of data is a pre-requisite for the regression model, the Kolmogorov-Smirnov test was used for this study.

To apply general regression analysis, the variance analysis method was used and in this method F tests were applied. General regression implies the simultaneous evaluation of all regression variables except fixed amounts.

The F amount for the regression model of the sample was obtained from the following equation:

Data Analysis

First Hypothesis: A significant relationship exists between firm performance and the Board Size.

Criteria selected for performance included ROA and ROE indices. Therefore the hypothesis was divided into two subsidiary hypotheses independent of each other:

A. A significant relationship exists between the ROA and the Board Size.

Regression running for this hypothesis is as follows:

$$ROA_{i,t} = \beta_0 + \beta_1 \, BRDSIZE + \beta_2 \, LOG(BVTA_{i,t}) + \beta_3 \, LEV_{i,t} + €$$

ROA: Return on Assets

BRDSIZE: Board Size

LOG (BVTA): Logarithm of the book value of assets

LEV: Leverage

Results from testing the hypotheses were presented in Table 1.

Table 1: Statistical results of the model for ROA (2002-2006)

Durbin-Watson Stat	Prob(F)	F	R^2	R	Prob(t)	T	β	Variable
					0.9317	-0.0858	-0.0282	Intercepts
					0.0014	-3.2194	-0.1780	Board Size
1.7515	0.0000	14.7013	0.1054	0.1131	0.9781	0.0274	0.0000	Company Size
					0.0000	-6.0409	-1.2990	Financial Leverage

Since the amount reflected for Prob(F) is less than 0.05, the regression can be considered as significant. This means that coefficients of regression variables were not simultaneously zero. Moreover the amount reflected Prob(t) for Board Size and financial leverage was less than 0.05, meaning that the coefficients of these variables are significant and that the Board Size affects ROA .

R^2 is approximately equal to 11% , meaning that 11 percent of the changes in ROA would be explained through the independent variable called the Board Size.

The final running of the regression model resulted in the following equation:

$$ROA_{i,t} = - 0,0282 + - 0,1780 \text{ BRDSIZE} + -1,2990 \text{ LEV}_{i,t}$$

Since the slope (β_1) is negative and equal to 0.1780; therefore changes in ROA are not parallel with changes in the Board Size and one unit of change in the Board Size would result in 0.1780 units of change in ROA.

The Durbin-Watson parameter is equal to 1.7515 which is between the 1.5 and 2 range. Therefore the probability of a correlation between the remainders is null, meaning that the remainders are independent of each other.

B. A significant relationship exists between ROE and the Board Size.

Regression running for this hypothesis is as follows:

$$ROE_{i,t} = \beta_0 + \beta_1 \text{ BRDSIZE} + \beta_2 \text{ LOG}(BVTA_{i,t}) + \beta_3 \text{ LEV}_{i,t} + €$$

ROE: Return on Equity

Results from testing the hypotheses were presented in Table 2.

Table 2: Statistical results of the model for ROE (2002-2006)

Durbin-Watson Stat	Prob(F)	F	R^2	R	Prob(t)	T	β	Variable
1.6561	0.0002	6.8454	0.0478	0.0560	0.6444	-0.4619	-0.2016	Intercepts
					0.0016	-3.1771	-0.2310	Board Size
					0.0810	1.7503	0.0000	Company Size
					0.0075	2.6875	0.7759	Financial Leverage

Since the amount reflected for Prob(F) is less than 0.05, the regression can be considered as significant. This means that coefficients of regression variables were not simultaneously zero. Moreover the amount reflected Prob(t) for Board Size and Financial

Leverage was less than 0.05, meaning that the coefficients of these variables are significant and that the Board Size affects ROE .

R^2 is approximately equal to 4%, meaning that 4 percent of the changes in ROE would be explained through the independent variable called the Board Size.

The final running of the regression model resulted in the following equation:

ROE $_{i,t}$ = - 0.2016 + 0.2310 BRDSIZE + 0.7759 LEV $_{i,t}$

Since the slope (β_1) is negative and equal to 0.2310; therefore changes in ROE are not parallel with changes in the Board Size and one unit of change in the Board Size would result in 0.2310 units of change in ROE, if operational leverage is kept constant.

The Durbin-Watson parameter is equal to 1.6561 which is between the 1.5 and 2 range. Therefore the probability of a correlation between the remainders is null, meaning that the remainders are independent of each other.

Second Hypothesis: A significant relationship exists between firm performance and the proportion of external members of the board.

The hypothesis was again divided into two subsidiary hypotheses using both ROA and ROE as operational indices; the two new hypotheses have been tested independently.

A. A significant relationship exists between ROA and the proportion of external members of the board.

Regression running for this hypothesis is as follows:

ROA $_{i,t}$ = β_0 + β_1 BRDEXT $_{i,t}$ + β_2 LOG(BVTA) + β_3 LEV $_{i,t}$ + $\epsilon_{i,t}$

BRDEXT: the proportion of external members of the board

Results from testing the hypotheses were presented in Table 3.

Table 3: Statistical results of the model for ROA (2002-2006)

Durbin-Watson Stat	Prob(F)	F	R^2	R	Prob(t)	T	β	Variable
					0.0000	-5.2298	-0.9516	Intercepts
1.7479	0.0000	11.5894	0.0834		0.8031	-0.2496	-0.0454	Proportion of External Members of the Board

| | | | | | 0.9111 | -0.1118 | 0.0000 | Company Size |
| | | | | | 0.0000 | -5.7546 | -1.2424 | Financial Leverage |

Since the amount reflected for Prob(F) is less than 0.05, the regression can be considered as significant. This means that coefficients of regression variables were not simultaneously zero. Moreover the amount reflected Prob(t) for the proportion of External Members and Company Size was more than 0.05, meaning that the coefficients of these variables are not significant and that the proportion of external members of the board does not affect ROA.

The final running of the regression model resulted in the following equation:

$$ROE_{i,t} = -0.9516 + -1.2424 \, LEV_{i,t}$$

Since the independent variable is not significant, therefore the estimated model includes a control variable called the operational leverage. Therefore changes in ROA cannot be predicted.

The Durbin-Watson parameter is equal to 1.7515 which is between the 1.5 and 2 range. Therefore the probability of a correlation between the remainders is null, meaning that the remainders are independent of each other.

B. A significant relationship exists between ROE and the proportion of external members of the board.

Regression running for this hypothesis is as follows:

$$ROE_{i,t} = \beta_0 + \beta_1 \, BRDEXT_{i,t} + \beta_2 \, LOG(BVTA) + \beta_3 \, LEV_{i,t} + \text{€}_{i,t}$$

BRDEXT: the proportion of external members of the board.

Results from testing the hypotheses were presented in Table 4.

Table 4: Statistical results of the model for ROE (2002-2006)

Durbin-Watson Stat	Prob(F)	F	R^2	R	Prob(t)	T	β	Variable
					0.0000	-6.1267	-1.4289	Intercepts
					0.9765	0.0295	0.0066	Proportion of External Members

								of the Board
1.6532	0.0058	4.2461	0.0271	0.0354	0.0614	1.8765	0.0000	Company Size
					0.0041	2.8862	0.8278	Financial Leverage

Since the amount reflected for Prob(F) is less than 0.05, the regression can be considered as significant. This means that coefficients of regression variables were not simultaneously zero. Moreover the amount reflected Prob(t) for the proportion of external members of the board and company size was more than 0.05, meaning that the coefficients of these variables are not significant and that the proportion of external members of the board does not affect ROA.

The final running of the regression model resulted in the following equation:

$ROE_{i,t} = -1.4289 + 0.8278\ LEV_{i,t}$

Since the independent variable is not significant, therefore the estimated model includes a control variable called the operational leverage. Therefore changes in ROE cannot be predicted.

The Durbin-Watson parameter is equal to 1.6532 which is between the 1.5 and 2 range. Therefore the probability of a correlation between the remainders is null, meaning that the remainders are independent of each other.

Third Hypothesis: A significant relationship exists between firm performance and the proportion of common stocks owned by major shareholders.

The indices used for measuring performance were ROA and ROE. Therefore the hypothesis was again divided into two subsidiary hypotheses which have been tested independently.

   A. A significant relationship exists between ROA and the proportion of common stocks owned by major shareholders.

Regression running for this hypothesis is as follows:

$ROA_{i,t} = \beta_0 + \beta_1\ FINAN_{i,t} + \beta_2\ LOG(BVTA) + \beta_3\ LEV_{i,t} + \epsilon_{i,t}$

FINAN: the proportion of common stocks owned by major shareholders

Results from testing the hypotheses were presented in Table 5.

Table 5: Statistical results of the model for ROA (2002-2006)

Durbin-Watson Stat	Prob(F)	F	R^2	R	Prob(t)	T	β	Variable
1.6532	0.0058	4.2461	0.0271	0.0354	0.0000	-6.1267	-1.4289	Intercepts
					0.9765	0.0295	0.0066	Proportion of common stocks owned by Major Shareholders
					0.0614	1.8765	0.0000	Company Size
					0.0041	2.8862	0.8278	Financial Leverage

Since the amount reflected for Prob(F) is less than 0.05, the regression can be considered as significant. This means that coefficients of regression variables were not simultaneously zero. Moreover the amount reflected Prob(t) for proportion of common stocks owned by major shareholders and financial leverage was less than 0.05, meaning that the coefficients of these variables are significant and that the proportion of stocks owned by major shareholders affects ROA.

R^2 is approximately equal to 13%, meaning that 13 percent of the changes in ROA would be explained through the independent variable called the proportion of common stocks owned by major shareholders.

The final running of the regression model resulted in the following equation:

$$ROA_{i,t} = -1.8602 + 0.0115\ FINAN_{i,t} + 1.3453\ LEV_{i,t}$$

Since the slope (β_1) is positive and equal to 0.0115; therefore changes in ROA are not parallel with changes in the proportion of common stocks owned by major shareholders and one unit of change in the proportion would result in 0.0115 units of change in ROA, if operational leverage is kept constant.

The Durbin-Watson parameter is equal to 1.7571 which is between the 1.5 and 2 range. Therefore the probability of a correlation between the remainders is null, meaning that the remainders are independent of each other.

B. A significant relationship exists between ROE and the proportion of common stocks owned by major shareholders.

Regression running for this hypothesis is as follows:

$$\text{ROE}_{i,t} = \beta_0 + \beta_1 \text{FINAN}_{i,t} + \beta_2 \text{LOG(BVTA)} + \beta_3 \text{LEV}_{i,t} + \text{\euro}_{i,t}$$

FINAN: the proportion of common stocks owned by major shareholders

Results from testing the hypotheses were presented in Table 6.

Table 6: Statistical results of the model for ROE (2002-2006)

Durbin-Watson Stat	Prob(F)	F	R^2	R	Prob(t)	T	β	Variable
					0.0000	-7.6075	-2.4153	Intercepts
					0.0002	3.7741	0.0128	Proportion of common stocks owned by Major Shareholders
1.6163	0.0000	10.0013	0.0718	0.0798	0.0565	1.9133	0.0000	Company Size
					0.0102	2.5834	0.7295	Financial Leverage

Since the amount reflected for Prob(F) is less than 0.05, the regression can be considered as significant. This means that coefficients of regression variables were not simultaneously zero. Moreover the amount reflected Prob(t) for proportion of common stocks owned by major shareholders and financial leverage was less than 0.05, meaning that the coefficients of these variables are significant and that proportion of common stocks owned by major shareholders affects ROE.

R^2 is approximately equal to 7%, meaning that 7 percent of the changes in ROE would be explained through the independent variable called the proportion of common stocks owned by major shareholders.

The final running of the regression model resulted in the following equation:

$$\text{ROE}_{i,t} = -2.4153 + 0.0128 \text{FINAN}_{i,t} + 0.7295 \text{LEV}_{i,t}$$

Since the slope (β_1) is positive and equal to 0.0128; therefore changes in ROE are parallel with changes in the proportion of common stocks by Major Shareholders and one unit of change in the proportion would result in 0.0128 units of change in ROE, if operational leverage is kept constant.

The Durbin-Watson parameter is equal to 1.6163 which is between the 1.5 and 2 range. Therefore the probability of a correlation between the remainders is null meaning that the remainders are independent of each other.

Fourth Hypothesis: A significant relationship exists between firm performance and the proportion of common stocks owned by individual shareholders (Free Float Shares).

The hypothesis was again divided into two subsidiary hypotheses using both ROA and ROE as operational indices; the two new hypotheses have been tested independently.

- A significant relationship exists between ROA and the proportion of common stocks owned by individual shareholders (Free Float Shares).

- Regression running for this hypothesis is as follows:

$$ROA_{i,t} = \beta_0 + \beta_1\ INDIV_{i,t} + \beta_2\ LOG(BVTA) + \beta_3\ LEV_{i,t} + \text{€}_{i,t}$$

INDIV: the proportion of common stocks owned by individual shareholders (Free Float Shares)

Results from testing the hypotheses were presented in Table 7.

Table 7: Statistical results of the model for ROA (2002-2006)

Durbin-Watson Stat	Prob(F)	F	R^2	R	Prob(t)	T	β	Variable
1.7569	0.0000	19.2220	0.2089	0.2204	0.0223	-2.3030	-0.3814	Intercepts
					0.0007	-3.4286	-0.0093	Proportion of Free Float Shares
					0.9740	-0.0326	0.0000	Company Size
					0.0000	-7.7845	-1.8487	Financial Leverage

Since the amount reflected for Prob(F) is less than 0.05, the regression can be considered as significant. This means that coefficients of regression variables were not simultaneously zero. Moreover the amount reflected Prob(t) for the proportion of common stocks owned by individual shareholders and financial leverage was less than 0.05, meaning that the coefficients of these variables are significant and that the proportion of free float shares affects ROA. R^2 is approximately equal to 21% meaning that 21 percent of the changes in ROA would be explained through the independent variable called the proportion of free float shares.

The final running of the regression model resulted in the following equation:

$$ROA_{i,t} = -0.3814 + -0.0093\ INDIV_{i,t} + -1.8487\ LEV_{i,t}$$

Since the slope (β_1) is negative and equal to 0.0093; therefore changes in ROA are not parallel with changes in the proportion of free float shares and one unit of change in the proportion of free float shares would result in 0.0093 units of change in ROA, if operational leverage is kept constant.

The Durbin-Watson parameter is equal to 1.7569 which is between the 1.5 and 2 range. Therefore the probability of a correlation between the remainders is null, meaning that the remainders are independent of each other.

A. A significant relationship exists between ROE and the proportion of free float shares.

Regression running for this hypothesis is as follows:

$$ROE_{i,t} = \beta_0 + \beta_1\ INDIV_{i,t} + \beta_2\ LOG(BVTA) + \beta_3\ LEV_{i,t} + \mathcal{E}_{i,t}$$

INDIV: the proportion of common stocks owned by individual shareholders (free float shares)

Results from testing the hypotheses were presented in Table 8.

Table 8: Statistical results of the model for ROE (2002-2006)

Durbin-Watson Stat	Prob(F)	F	R^2	R	Prob(t)	T	β	Variable
1.6474	0.0408	2.8060	0.0254	-0.0394	0.0010	-3.3399	-0.7796	Intercepts
					0.0172	-2.4016	-0.0090	Proportion of Free Float Shares
					0.2579	1.1346	0.0000	Company Size
					0.6823	0.4098	0.1398	Financial

							Leverage

Since the amount reflected for Prob(F) is less than 0.05, the regression can be considered as significant. This means that coefficients of regression variables were not simultaneously zero. Moreover the amount reflected Prob(t) for the proportion of free float shares and financial leverage was less than 0.05, meaning that the coefficients of these variables are significant and that the ratio of free float shares affects ROE.

R^2 is approximately equal to 3% meaning that 3 percent of the changes in ROE would be explained through the independent variable called the proportion of free float shares.

The final running of the regression model resulted in the following equation:

$$\text{ROE}_{i,t} = -0.7796 +- 0.0090 \ \text{INDIV}_{i,t}$$

Since the slope (β_1) is negative and equal to 0.0090; therefore changes in ROE are not parallel with changes in the proportion of free float shares and one unit of change in the proportion of free float shares would result in 0.0090 units of change in ROE.

The Durbin-Watson parameter is equal to 1.6474 which is between the 1.5 and 2 range. Therefore the probability of a correlation between the remainders is null, meaning that the remainders are independent of each other.

General Regression Tests

The general regression was presented as follows:

$$\text{Performance}_{i,t} = \beta0 + \beta_1 \ \text{BRDSIZE}_{i,t} + \beta_2 \ \text{BRDEXT}_{i,t} + \beta_3 \ \text{FINAN}_{i,t} + \beta_4 \ \text{INDIV}_{i,t} + \beta_5 \ \text{LOG(BVTA)}_{i,t} + \beta_6 \ \text{LEV}_{i,t} + \epsilon_{i,t}$$

Since information relating to free float shares have been available since the year 2004, the research was confined to the years 2004-2006. Performance criteria used in the research were ROA and ROE, therefore the general regression equation has been defined as follows:

A) $\text{ROA}_{i,t} = \beta_0 + \beta_1 \ \text{BRDSIZE}_{i,t} + \beta_2 \ \text{BRDEXT}_{i,t} + \beta_3 \ \text{FINAN}_{i,t} + \beta_4 \ \text{INDIV}_{i,t} + \beta_5 \text{LOG(BVTA)}_{i,t} + \beta_6 \ \text{LEV}_{i,t} + \epsilon_{i,t}$

B) $\text{ROE}_{i,t} = \beta_0 + \beta_1 \ \text{BRDSIZE}_{i,t} + \beta_2 \ \text{BRDEXT}_{i,t} + \beta_3 \ \text{FINAN}_{i,t} + \beta_4 \ \text{INDIV}_{i,t} + \beta_5 \ \text{LOG(BVTA)}_{i,t} + \beta_6 \ \text{LEV}_{i,t} + \epsilon_{i,t}$

Results from testing regression A have been reflected in the Table 9.

Table 9: Statistical results of the general model for ROA (2002-2006)

Durbin-Watson Stat	Prob(F)	F	R^2	R	Prob(t)	t	β	Variable
1.637	0.00	11.872	0.241	0.263	0.733	0.613	-0.209	Intercepts
					0.346	0.004	-0.004	Proportion of Free Float Shares
					0.013	0.005	0.011	Proportion of common stocks owned by Major Shareholders
					0.002	0.079	-0.249	Board Size
					0.686	0.245	0.099	Proportion of External Members of the Board
					0.809	0.00	0.00	Company Size
					0.00	0.238	-1.910	Financial Leverage

Since the amount reflected for Prob(F) is less than 0.05, the regression can be considered as significant. This means that coefficients of regression variables were not simultaneously zero. Moreover the amount reflected Prob(t) for the proportion of stocks owned by Major Shareholders and the Board Size was less than 0.05, meaning that the coefficients of these variables are significant and that the proportion of stocks owned by Major Shareholders and the Board Size affects ROA.

R^2 is approximately equal to 24%, meaning that 24 percent of the changes in ROA would be explained through the independent variables called the proportion of stocks owned by Major Shareholders and the Board Size.

The final running of the regression model resulted in the following equation:

$ROA_{i,t}$ = -0.249 $BRDSIZE_{i,t}$ + 0.011 $FINAN_{i,t}$ + -1.910 $LEV_{i,t}$

Since the slope (β_1) is negative and equal to 0.249; therefore changes in ROA are not parallel with changes in Board Size and one unit of change in the Board Size would result in 0.249 units of change in ROA.

The Durbin-Watson parameter is equal to 1.637 which is between the 1.5 and 2 range. Therefore the probability of a correlation between the remainders is null, meaning that the remainders are independent of each other.

Results from testing regression B have been presented in Table 10.

Durbin-Watson Stat	Prob(F)	F	R^2	R	Prob(t)	t	B	Variable
					0.311	1.074	-1.090	Intercepts
					0.935	0.005	0.00	Proportion of Free Float Shares
					0.011	0.007	0.017	Proportion of stocks owned by Major Shareholders
1.996	0.00	22.278	0.062	0.089	0.049	0.138	-0.269	Board Size
					0.702	0.312	0.120	Proportion of External Members of the Board
					0.241	0.00	0.00	Company Size
					0.793	0.346	0.091	Financial Leverage

Since the amount reflected for Prob(F) is less than 0.05, the regression can be considered as significant. This means that coefficients of regression variables were not simultaneously zero. Moreover the amount reflected Prob(t) for the proportion of stocks owned by Major Shareholders and the Board Size was less than 0.05, meaning that the coefficients of these variables are significant and that the proportion of stocks owned by Major Shareholders and the Board Size affects ROE.

R^2 is approximately equal to 6%, meaning that 6 percent of the changes in ROE would be explained through the independent variables called the proportion of stocks owned by Major Shareholders and the Board Size.

The final running of the regression model resulted in the following equation:

$$ROE_{i,t} = -0.269 \ BRDSIZE_{i,t} + 0.017 \ FINAN_{i,t}$$

Since the slope (β_1) is negative and equal to 0.269; therefore changes in ROE are not parallel with changes in Board Size and one unit of change in the Board Size would result in 0.269 units of change in ROE.

The Durbin-Watson parameter is equal to 1.996 which is between the 1.5 and 2 range. Therefore the probability of a correlation between the remainders is null, meaning that the remainders are independent of each other.

Conclusion

The present research attempted to discover a relationship between criteria selected for corporate governance and performance. For this purpose research hypotheses were designed using four criteria for corporate governance and two indices for measuring performance. Results from testing the hypotheses reflected that except for the relationship between the proportion of External Members of the Board with performance (second hypothesis), the other relationships are significant.

It seems that even though the presence of External Members in board composition should enhance performance; in Iran due to the short history of corporate governance, this issue has not yet been fully understood and/or executed. In previous studies performed in Iran, same results have been achieved (Rezayi, 2007; Ghanbari, 2007).

In other countries as well, most studies have shown a significant relationship between the presence of External Members of the Board and firm performance (Dehaene, 2001; Lefort et al., 2007; Krivogorsky, 2007). This may be due to the long history of applying corporate governance in these countries.

Results from applying the general regression tests indicate that the variables named the proportion of Free Float shares and the proportion of External Members of the Board do not influence firm performance. It seems that the two most significant factors in the issue of corporate governance, that is the presence of external Members in the composition of the board and Free Float shares have not yet had an executive effect, and thus do not influence firm performance.

CORPORATE GOVERNANCE AND BOARD PERFORMANCE: EVIDENCE FROM PUBLIC LISTED COMPANIES IN MALAYSIA

Hasnah Kamardin, Universiti Utara Malaysia,
Hasnah Haron, Universiti Sains Malaysia

ABSTRACT

This study examines the relationship between internal corporate governance mechanisms and board performance for a sample of 112 companies listed on Bursa Malaysia. Board performance is measured in terms of board of directors' participation in executing their roles in the year 2006. The corporate governance mechanisms considered in this study are board attributes and managerial ownership. The relationship between corporate governance and board performance shows non-independent non-executive directors and managerial ownership are significantly related to strategy, management oversight and performance evaluation roles. Multiple directorships are found negatively related to strategy roles whilst independent board leadership is negatively related to management oversight board. Only managerial ownership is found to be related to service roles. To some extent, corporate governance mechanisms do affect board performance of Malaysian listed companies. Some findings have implications to the revised code of corporate governance.

Keywords: governance mechanisms, board attributes, board performance.

Introduction

Due to weak market control in emerging countries, internal corporate governance mechanisms play a vital role in corporate governance of emerging markets (Lei & Song, 2004). Two important internal corporate governance mechanisms are board of directors (BOD) and directors' shareholding. Board characteristics and ownership structure are considered to have influence on the decisions made by the managers (Lemmons & Lins,

2003). Firm's ownership structure is said to be the primary determinant of the extent of agency problems between controlling insiders and outside investors.

However, having good corporate governance (board conformance) does not necessarily ensure high board performance as the design of internal mechanisms of a firm is based on company's needs (CMA, 2002; Nicholson & Kiel, 2004). In addition, emphasis on specific role varies depending on the inputs (Nicholson & Kiel, 2004). It is expected that the corporate governance mechanisms would have some impact on the roles played by the board of directors (a proxy of board performance). Whether the board can perform well or not will depend on the corporate governance mechanisms adopted. Thus, the objective of the present study is to examine the impact of internal corporate governance mechanisms (BOD attributes and directors' shareholding) on board performance. The findings of this study would provide some evidence on the implication of some recommendations of the revised code of corporate governance (revised code) in 2007 on the effectiveness of board performance.

Review of Literature

Corporate Governance in Malaysia

Efforts to improve corporate governance practices in public listed companies in Malaysia started in 1987 with the establishment of Federation of Public Listed Companies Bhd (FPLC) which was recognized as the official spoke person for PLCs in Malaysia. The establishment of audit committee in a company was made mandatory by the KLSE Listing Requirements in 1994. However, the emphasis on corporate governance practices was only highlighted after the Asian Financial Crisis 1997 with the introduction of Malaysian Code of Corporate Governance (MCCG Code) in 1999. The purpose of the code is to set out principles and best practices on structures and processes that companies may use to achieve optimal governance framework.

683

Public companies are required to adhere to the principles of the code based on varying circumstances of individual companies. The code became effective to public listed companies after the revamp of KLSE Listing Requirements in 2001. Accordingly, Bursa Malaysia has made it mandatory for public companies to adhere to Chapter 15 of Corporate Governance related to Directors, Audit Committee, Auditors and Corporate Governance Disclosure.

The MCCG Code was revised in 2007 with the aim to strengthen the roles and responsibilities of the BOD and audit committee to ensure they can discharge their duties effectively (SC, 2007). Among other amendments, the revised code places importance on the process carried out by the nominating committee in evaluating members of the board. The revised code requires the board to properly document issues and decisions discussed in a meeting. BOD should implement a process to be carried out annually for assessing the effectiveness of BOD, of committees of the board, and the contribution of each individual director. The code also provides clarity on criteria that should be considered by the nominating committee when recommending candidates of directorships. The proposed criteria are:

a. skills, knowledge, expertise and experience;

b. professionalism;

c. integrity; and

d. candidate's ability to discharge such responsibilities.

Theoretical Perspectives on Board of Directors' Roles

Board performance refers to the ability of directors to perform board roles (Ong & Lee, 2000; Wan & Ong, 2005). According to Nicholson and Kiel (2004) an effective board is "…one that can successfully execute the role set required of it" (p. 453). Nicholson and Kiel also argue that the ability of the board to execute these roles will determine how

effective the board governs the company. As board effectiveness will be based on board performance, board roles will be used as proxy for board performance in the present study.

Refer to Table 1- Theoretical Perspectives on Board of Directors' Roles

Table 1 outlines some theoretical perspectives on board roles and their respective operational definitions. For specific roles of the board of directors, related prominent theory perspectives such as legalistic perspective, agency theory, stewardship theory, and resource dependency theory are consulted. The study uses agency theory, stewardship theory, and resource dependency perspective to conceptualize the roles of BOD. In the present study, four dimensions of BOD roles are adopted following MCCG Code (FCCG, 2001), Wan and Ong (2005), Brennan (2005), and Ingley and Van der Walt (2005). Four dimensions of BOD roles are proposed in the present study i.e. strategy, monitoring, service, and resource dependency roles.

Board of Directors (BOD)

Zahra and Pearce (1989) identify four attributes of BOD which lead to good performance of firms: board composition, characteristics, structure, and process. The board composition refers to the board size and the mix of director types (insiders vs. outsiders). Board characteristics consist of two components which are directors' background (age, educational background, values, and experience) and board personality. Board structure refers to the dimensions of board's organization which include types of committees, committee membership, flow of information, and board leadership. Board process is referred to the approach the board takes in making decisions.

Board attributes that have been studied most in the corporate governance research are the board composition and board structure. In the management research, focus of studies is on the characteristics of board to link the CEO or executive directors'

background and personalities to the firm performance. The board process is less studied due to the difficulty of getting data about the activities and styles of board in making decisions. Vafeas (1999) was the first study to proxy the board process using the frequency of board meeting. The current study adopts all the board attributes suggested by Zahra and Pearce (1989) i.e. board composition (board size and director's type), board characteristics (knowledge/experience: tenure and multiple directorships), and board structure (board leadership).

Ownership Structure in Malaysia

Corporate governance in Malaysia is greatly influenced by ownership structure which has been found to have impact on board composition, board practices and board decisions (Tan, 2005). Shareholding in Malaysian PLCs is highly concentrated in the hands of a few numbers of shareholders (Fazilah, 2002; La-Porta et al., 2000). As of December 1998, Fazilah (2002) reported that the mean of the first largest shareholding was 30.30% and that of the five largest shareholding was 58.84%, which accounted for more than half of the voting shares. About 71.4% of companies (Main Board and Second Board) were under majority ownership, having a shareholding of more than 50%, and were controlled by their five largest shareholders.

The significant means of enhancing control in Malaysia is through pyramid-holding, cross-holding and managerial ownership (Claessens, Djankov, & Lang, 2000). There is significant participation of owners in management with 33% of them involved in management (KLSE-PWC, 1999). The concentrated shareholding in PLCs is also dominated by family. Eighty five percent (85%) of the sample companies of Claessens, Djankov, and Lang (2000) had their CEO, board chairman or vice-chairman from a controlling family. The percentage of family control is 57.5% and 67.2%, at 10% cutoff

686

and 20% cutoff, respectively. Family also has the highest control in large companies (35%) and smaller companies (84%).

Corporate Governance and Board Performance

Board Size

As BOD is the central internal control mechanism for monitoring managers, monitoring ability of a board is said to be affected by board size, board composition and board leadership structure (Jensen, 1993). Agency theory argues that smaller boards are more effective than larger boards in monitoring managers (Jensen & Meckling, 1976). Studies on the monitoring roles of BOD in earnings management have shown the effectiveness of small board size (Bradbury, Mak, & Tan, 2006; Rashidah & Fairuzana Haneem, 2006). Previous studies in relation to firm performance have also shown the effectiveness of small board size (Conyon & Peck, 1998; Mak & Li, 2001; Singh & Davidson, 2003; Yermack, 1996). The relationships between board size and board's involvement in strategic decision making have been found to be negative (Carpenter & Westphal, 2001; Goodstein et al., 1994; Judge & Zeithaml, 1992; Ruigrok et al., 2006). Since strategic board involvement requires active directors, thus larger boards would mean more time required to capitalize or to consider on diversifying perspectives. Small board size is also effective to represent companies to the outside parties or public at large to be known as companies' representatives. For resource dependency roles, large boards mean that more representatives from outside directors, thus they are expected to provide more resources to the boards in executing their roles.

H1: There is a relationship between board size and board performance.

Board Leadership

Power plays a major role in strategic decision making and the board power is limited compared to the CEO (Stiles, 2001) because CEO has structural power and is an expert in firm's operations compared to the outside directors. As management team is usually headed by the CEO or managing director, who is responsible for the formulation of strategy (Van der Berghe & Baelden, 2005), having CEO duality would provide better strategy roles. However, independent leadership is expected to contribute to better monitoring of management and of strategy implementation. Boards are less likely to exert control over management when they lack independence from the management (Carpenter & Westphal, 2001). There should be a clear division of roles and responsibility between CEO and directors. Evidence on the relationship between CEO duality and earnings management activities are mixed. Deachow, Sloan and Sweeney (1996) which examine the relation between earnings manipulation and weaknesses in firm's internal governance in the U.S. show that boards with CEO duality practices and boards dominated by management are more likely to manipulate earnings. However, Xie, Davidson, and Dadalt (2003) found CEO duality is negatively related to earnings management activities. As CEOs determine the agenda for board meetings and they lead the discussion, thus having independent board leadership is critical as check and balance purposes before proposals are approved. Norman, Takiah and Mohd-Mohid (2005) found CEO duality firms were associated with earning management activities. Ruigrok et al. (2006) found a negative relationship between CEO duality and board's involvement in strategic decision making. The same goes to monitoring roles as independent board leadership would promote audit committee effectiveness. Having independent board leadership would be expected to lead to increased service and resource dependency roles as independent leadership reduces the agency costs (i.e. managerial entrenchment) related to CEO duality.

688

H2: There is a positive relationship between independent board leadership and board performance.

Non-independent Non-executive Directors

Hermalin and Weisbach (1988) suggest that the effectiveness of board monitoring also depends on the composition of the board. The quality of internal control system, which is under the internal audit function, has an effective impact on the monitoring process (Faudziah Hanim, Hasnah & Muhamad, 2005). Outside directors play important role to ensure a company has an effective internal control system. It is done through their involvement in an audit committee in which they have direct contact with the internal audit function.

A special report on non-executive directors by The Economist (20 March 2003, pp 71-73) highlights a special breed of non-executive directors who are non-independent, the so-called "gray" or affiliated directors. Apart from being non-executive, an affiliated director is usually an ex-employee, related to the firm's controlling family, an interlocking director, or a professional with significant business or family ties with the firm (Klien, 1998). As most of the gray or affiliated directors owns significant shares in the companies, their incentives to get involved and engaged in corporate governance are higher (Roberts, McNulty & Stiles, 2005). In addition, since affiliated directors have prior associations with the firm, they often have deeper knowledge of the firm and its industry than independent directors, and thus shareholders may feel affiliated directors instead of independent directors are better serving them. To be effective in monitoring strategic decisions, outside directors should be persons from the business (CEO or executive directors from other companies) with relevant knowledge and related expertise (Pettigrew & McNulty, 1995).

H3: There is a positive relationship between the non-independent non-executive directors and board performance.

Multiple Directorships

Directors with more multiple directorships are expected to have more exposure on certain tasks and procedures which can be implemented in another company, making board performance more effective because less transaction costs incurred (Beasey, 1996; Norman et al., 2005; Sarkar & Sarkar, 2005; Tan, 2005). They are expected to provide effective monitoring. Directors who have experience in related strategies are more capable of contributing to strategic decision process (Carpenter & Westphal, 2001). However, directors have less time to closely scrutinize the internal control system which leads to less effectiveness in monitoring the managers. Thus, they put more reliance on the work of the internal audit (Faudziah Hanim et al., 2005). Thus, directors with many multiple directorships may be limited by their time to play their roles effectively (Haniffa & Hudaib, 2006; Murphy & McIntyre, 2007).

H4: There is a negative relationship between multiple directorships and board performance.

Board Knowledge

Lorsch (1995) acknowledges that the board ability to govern also depends on the knowledge of directors. Knowledge of directors comes from their working experience. BODs with higher board knowledge are expected to execute their roles better. Fairchild and Li (2005) found board knowledge in terms of director's age and tenure had a positive relation to firm performance. Dionne and Triki (2005) found a positive relationship between board knowledge (financially educated) and risk management activities of BODs. Peasnell et al. (2001) found the tenure of non-executive directors is

690

negatively associated with the level of earning management activities which indicates the importance of board tenure in performing effective monitoring roles. As longer tenure would mean the CEO-board friendship ties increase, longer tenure would be expected to lead to increasing in services provided by the BOD to the management (Westpal, 1999). However, an optimal board tenure is required as long board tenure results in declining performance due to impediments such as increased social cohesion and decreased innovation adaption (Bantel & Jackson, 1989).

H5: There is a positive relationship between board knowledge and board performance.

Board Process

In terms of board process, frequency of board meetings is considered as one way board can contribute to formulating and implementing of strategy roles and monitoring roles (Davies, 1991; Vafeas, 1999). More board committee meetings are required to focus on specific issues especially when the companies are in poor performance which requires restructuring. Rather than focusing on frequency of board meetings, the present study uses percentage of meetings attendance as a proxy for board process. High percentage of meetings attendance would provide knowledge to directors about the business operations. Thus, expertise and knowledge of board members are highly demanded in strategic decision making, monitoring the strategy implementation and management control system, providing services to increase company reputation, and providing supplement resources to managers.

H6: There is a positive relationship between the board process and board performance.

Managerial Ownership

Agency theory views that managerial ownership (MOWN) may act as an incentive mechanism. High MOWN is expected to lead managers to maximize firm's wealth as the net effects will ultimately go to them. When the proportion of shares controlled by managers exceeds certain level, they may use their control over the corporation to generate their own private benefits (Morck et al., 1988; Shleifer & Vishny, 1997). Ownership concentration by managers is a factor that has impact on the monitoring potentials of BOD (Nicholson & Kiel, 2004). The presence of controlling shareholder is found to be associated with positive firm performance in Thailand (Wiwattanakantang, 2001). Companies with concentrated ownership might also be subjected to high monitoring activities as the tendency for entrenchment is higher (Ali & Sanda, 2002; Fauzias et al., 1999; Morck et al., 1988). Companies with high managerial ownership would be expected to provide high board performance as their actions will affect their wealth.

H7: There is a positive relationship between managerial ownership (MOWN) and board performance.

Firm size was considered as a control variable as the board performance may be affected directly or indirectly by factors related to the nature of the firm. Controlling for size was necessary as percentage of managerial shareholding may be larger in small firms due to small outlay required in small firms.

Research Methodology

Population and Data Collection

The unit of analysis of this study is company and BOD was taken to represent the company. The population of this study is companies listed on the main board of Bursa

692

Malaysia for the year 2006. Only the main board companies were selected in order to control for other factors that might influence performance of companies in other boards such as size differences and risks. As the population of companies listed on the Main Board in the year 2006 was around 520 (excluding finance companies, PN4, PN17, companies listed after 2004), the sample size according to Roscoe (1975) for multivariate regression should preferably be one to ten (or more) for each variable tested, which requires a sample size of 90. However, for factor analysis of board performance a sample of 100 is preferred.

A survey method was used to collect data on board performance from the BODs. Bearing in mind of the poor response rate generally obtained in survey studies conducted in Malaysia, which is about 10% to 20%, questionnaires were sent to all 520 companies. This study used one initial mailing and two follow-ups procedures. In the actual survey, a questionnaire with introductory letters (to the company secretary and BOD) and a self-addressed envelope was sent to the company secretary. The company secretary was asked to direct the questionnaire to a member of BOD, who could be the chairman, the CEO/managing director (MD), an executive (ED) or a non-executive director (NED). Only a member of BOD is required to answer the survey questionnaire as the company's representative. The selected BOD is informed that he or she is representing the BOD. In the other cover letter to the BOD, instructions were also given on how to answer the questionnaire and the BOD was asked to return the completed questionnaire within a month period. To increase response rate, the non-respondents were sent follow-up letters emphasized the need for the research on board's roles and their invaluable contribution to the research.

Construction of Questionnaire

Board performance measures the extent of BOD participation or involvement in the companies' decision making. Items in the questionnaires related to the board performance were adapted from Brennan (2005), FCCG (2001), Ingley and Van der Walt (2005), and Wan and Ong (2005). First, the study considered the items from Wan and Ong's study as a basis as this study was conducted in Singapore which is similar in characteristics with Malaysian companies in terms of ownership structure and other board characteristics. Then comparisons were made between the roles of BOD from Wan and Ong's study with the roles of BOD as recommended in the Malaysian Code of Corporate Governance (MCCG Code) and also with available literature review on board roles.

After examining the board roles items closely, it was found that board roles in Wan and Ong's study fulfill most of the board roles stated in the MCCG Code. However, for strategy roles, it was found that Wan and Ong did not consider the role of risk management activities specifically whereas risk management activities are among the priority roles emphasized in the MCCG Code. Random checks were done in the annual reports of the main board companies in the sections of Corporate Governance Statement and in the Statement of Internal Control. They revealed that BODs in most cases undertake risk management activities. Thus, three items related to risk management as suggested by the MCCG Code were added ("identify principal risks of the company", "set risk appetite of the company", and "ensure implementation of appropriate systems to manage risks") in the questionnaire.

For the monitoring roles, most items were adapted from Wan and Ong, except item "evaluate the skill mix on the board" that was taken from the MCCG Code. Items "ensure corporate survivals", "specify lines of authority of management and board", and "review social responsibilities of the company" were from Brennan's. For service roles, three items from Brennan's ("enhance company reputation", "act as ambassador for the

694

company", and "participate in developing relationships with outside parties") were added whilst the rest were from Wan and Ong. For resource roles, three items were from Wan and Ong ("bring in skills relevant to the company", "provide a balanced/independent view onto the board", and "represent shareholders' interests effectively") and six items were from Ingley and Van der Walt's. In summary, the operational definitions of the BOD roles are as follows:

(1) Monitoring roles refer to the selection and reward of CEOs, evaluation of CEOs and company performance, and maximization of shareholders' wealth;

(2) Service roles refer to providing advice to top management and promoting reputation of the company externally;

(3) Strategy roles refer to strategic functions of board in terms of direction and planning including risk management; and

(4) Resource dependency roles refer to functions of outside directors.

In constructing the questionnaire, the content validity of the instrument was assessed based on the literature review and a pre-test study to BODs and senior academics. A preliminary study was conducted to refine and clarify questions and items in the instrument with regards to their meaning, clarity of each statement, relevance of items and problems encountered in completing the questionnaire. Feedbacks from five directors were considered. The questionnaire was also checked by two senior academics who have experience in survey research. Based on their suggestions, some modifications to the questionnaire were done. Then, a pilot study was conducted amongst 30 directors. In the questionnaire, six (6) demographic questions and 34 items on board performance (7 strategy, 11 monitoring, 7 service, and 9 resource) were asked. The demographic items asked the position of respondent in the company's BOD, type of non-executive directors, age of respondent, numbers of years respondent has been on

695

the board, educational background and other positions. For board performance variables (strategy, monitoring, services and resource), BOD was required to indicate the extent of BOD participation or involvement in the board roles of the company for the financial year 2006 using a 5-point scale ranging from 1 (*very little*) to 5 (*very much*) as used by Kula (2005) and other survey studies that examined participation in decision-making.

Data Analysis

For the board performance dimensions, factor analysis was conducted to determine the clusters of items fitting into a board performance dimension. The principal component analysis (PCA) in factor analysis was used for data reduction and to identify relevant factors. With a sample size of 112, the study used factor loading of 0.50 as suggested by Hair et al. (2006). In addition, factor loading of 0.5 and more is relevant for practical significance.

In deciding which items to be included in a factor, items that have high cross-loading in two or more variables are excluded. According to Hair et al. (2006), if a factor loading accepted is 0.50 and above, then an item which has cross-loading 0.50 and above is excluded. A difference of less than 0.10 in the cross-loading was considered as additional criteria to exclude an item from a factor (Snell & Dean, 1992).

Reliability analysis was run to determine the internal consistency (Cronbach Alpha) of items in a variable. Accordingly, the items in a variable should be measuring the same construct and thus be highly inter-correlated. To assess the internal consistency, the following series of diagnostic measures were considered (Hair et al., 2006):

(1) the reliability coefficient (Cronbach Alpha) accepted for this study is 0.7. Cronbach Alpha of 0.70 is generally agreed for lower limit, even though it may be decreased to 0.60 for exploratory research;

(2) item-to-total correlation (correlation of an item to the summated scale score) should be more than 0.5; and

(3) inter-item correlation (correlation among items) should be more than 0.30.

Regression analyses were conducted to examine the relationship between corporate governance mechanisms and each of board performance dimensions. The regression function is as follows:

$$BP = b_0 + b_1(BSIZE) + b_2(BLEAD) + b_3(NINE) + b_4(MMDIR) + b_5(TEN) + b_6(BPROS) + b_7(MOWN) + b_8(LGTA) + \varepsilon$$

Where:

BSIZE	number of board members
BLEAD	board leadership, dummy "1" for CEO ≠ Chairman, "0" otherwise
NINE	proportion of non-independent non-executive directors
MMDIR	directorships per director
TEN	average of directors' tenure
BPROS	frequency of board meetings or percentage of meeting attendance
MOWN	percentage of executive directors' shareholdings
BP	board performance dimensions
LGTA	logarithm of total assets

Results and Discussion

Sample Profile

Refer to Table 2 – Profile of Respondents

Out of 520 questionnaires sent, only 112 are usable which represents a response rate of 21.54%. In terms of composition of respondents, CEO/Managing Director represents the highest frequency of 36 (32.14%), followed by executive director of 30 (26.79%). The non-executive directors, comprising of independent directors and non-independent non-executive directors are 24 (21.43%). There are 11 (9.82%) company secretaries participated in the study. Responses from the company secretaries are also included in this study as they are key management positions akin to the CEOs (Zubaidah, 2002). In

697

most cases they usually respond on behalf of the directors. Furthermore, their nature of work and close working with the company directors justify them to be included in the study. In total, based on the type of director, 60.71% of the respondents represent the executive director (non-independent executive director) while 29.47% are the non-executive director (independent director and non-independent non-executive director).

In terms of years employed as BOD or working with BOD, nearly all respondents which are about 108 (96.4%) had more than three years experience. Thus, almost all respondents have enough experience in understanding the roles of BOD in their companies. About 60 (53.60%) respondents have educational background either in Finance, Economics or Business. Forty four respondents (39.30%) have degrees in other fields, which are usually related to the core business of the companies.

With respect to sector, almost all sectors are covered in this study. Nearly 80% of the respondents come from four sectors namely Industrial Product (IP), Trading and Services (TS), Construction (CONST) and Property (PROP).

The response bias analysis (t-test) for the board roles data was conducted for the early (N = 63) and the late (N = 49) responses to examine the homogeneity of samples. Late responses referred to responses received after the follow-ups were done. There is no significant difference between early and late responses for all board roles as shown by the insignificant t-value of each factor [STRATEGY ($t = 1.285$), REDEP1 ($t = -0.742$), SERVICE ($t = -0.032$), REDEP2 ($t = -0.864$), MONITOR1 ($t = -0.558$), MONITOR2 ($t = -0.101$)]. Thus, the response bias is not considered a significant issue in this study.

Descriptive Statistics of Variables

Refer to Table 3 - Descriptive Statistics of the Categorical Variable

Based on the common definition of board leadership (BLEAD), about 83.9% of the sample companies have different persons acting as CEO/MD and chairman of the

companies. Even though the MCCG Code recommends companies to have independent leadership, some companies (about 16.1%) still choose to opt the combined leadership structure.

Refer to Table 4 - Descriptive Statistics of the Continuous Variables

The average of board size (BSIZE) is 7.66 with the minimum of four directors and maximum of thirteen directors. The board size of the sample companies in this study is not much different from that in the study by PWC-KLSE (2002) of eight directors. The average proportion of non-independent non-executive directors (NINE) in a company is 0.24 (which is about two directors), with a minimum of 0.00 (no director) and a maximum of 0.67 (6 directors). The proportion of NINE in this study is quite low compared to that in the study by PWC (2002) of average three NINE in a public listed company.

Frequency meeting (FMEET) conducted is about 5.79 times per year with a minimum of four times to a maximum of fifteen times. It shows that more meetings were conducted even though companies are only required to have at least four meetings per financial year. The percentage meeting attendance of directors (PMEET) is quite high with the average of 93.70% and with the minimum of 75% and the maximum of 100%. By company, the average tenure (TEN) of directors serving on the board is about 7.79 years with a minimum serving of 1.25 year and maximum of 26.33 years. Individually, the maximum tenure of directors serving on the board reached up to 34 years. For multiple directorships (PMDIR), on average about 50% (48.43%) of the directors in a company have at least one additional directorship in other PLCs, with a minimum of 0.00 and a maximum of 100%. This is quite high compared to Tan's finding (2005) of 31.41% with a sample year of 2001. The multiple directorships per director (MMDR) in a company is 1.43 with a maximum of 4.67. Individually, the maximum multiple directorships held by directors reached up to the maximum limit of 10 directorships in PLCs. Some of them even have additional directorships in non-public listed companies,

699

societies and government agencies. For managerial ownership (MOWN), on average executive directors hold 23.80% shareholdings with a minimum holding of 0% and a maximum holding of 79.10%. The average shareholdings are not much different from Chee and Fauziah (2005) of 24.96%.

On average the board performance dimensions have more than 3.00 mean scores with MONITOR1 (management oversight roles) and REDEP2 (providing resources to management by outside directors) hold higher scores than the rest of the dimensions. However, MONITOR2 (performance evaluation roles) is less emphasized.

Roles of Board of Directors

Refer to Table 5 - Results of the Principal Component Analysis and Reliability Analysis of Board Performance

Results from the factor analysis extracted six dimensions of board roles instead of four dimensions proposed. The results differentiate monitoring roles i.e. management oversight roles (MONITOR1) from performance evaluation roles (MONITOR2). Resource dependency roles are further classified into two dimensions: protecting shareholders' and other stakeholders' interests (REDEP1) and providing resources to management (REDEP2). Strategy (STRATEGY) and maintaining company's reputation roles (SERVICE) remain as one factor each. The findings are in agreement with agency theory perspectives of the roles of BOD to get involved in the strategic decision process and control. The findings also support the argument by the Mintzberg (1983) that the roles of board of directors are to serve the organization in maintaining company's reputation. In addition, the findings also support Wan and Ong's (2005) finding to differentiate service roles from strategic roles as they are shown to be different dimensions.

700

However, the findings are somewhat different from the findings by Wan and Ong (2005) because their study identified only four dimensions of board performance i.e. strategy, service, monitoring, and resource dependency roles. The difference may be due to the instruments used to capture board performance items. In the present study the modified instruments were used. Several items were added to Wan and Ong's original instruments to measure roles and responsibilities of BOD according to the requirements of the MCCG Code and the literatures which are not captured in Wan and Ong's study.

Correlations among Variables

Refer to Table 6 - Pearson Correlation Matrix between Corporate Governance and Board Performance

In general, since all correlations are less than 0.80, there is no issue of multicollinerity between independent variables. Board size (BSIZE) is found positively correlated with firm size (LGTA) and the proportion of non-independent non-executive directors (NINE). However, board size is negatively correlated with the percentage of meeting attendance (PMEET), which means that companies with larger board size tend to have lower percentage of board meeting attendance. For board leadership (BLEAD), there is a positive correlation between board leadership and the proportion of non-independent non-executive directors (NINE) but a negative correlation between board leadership and the percentage of meeting attendance (PMEET). This means that companies with independent leadership tend to have more proportion of non-independent non-executive directors (NINE) but less percentage of meeting attendance (PMEET).

The proportion of non-independent non-executive directors (NINE) is found negatively correlated with managerial ownership (MOWN). Smaller companies tend to have higher managerial ownership (MOWN). Companies with higher managerial

ownership (MOWN) tend to have greater involvement in strategy and service roles. Directors with multiple directorships are more attached to larger companies. Directors with multiple directorships tend to have lower involvement in strategy roles. Larger companies tend to have more MONITOR1 and REDEP2.

Relationship between Corporate Governance and Monitoring Roles

Refer Table 7 - Multiple Regression Results between Corporate Governance and Monitoring Roles

Using standard regression analysis, the Breusch-Pagan (Cook-Weisberg) test shows that all models are significant with p-value less than 0.05 which suggests that heteroskedasticity was present in those models. Thus, regression analyses with robust option are adopted to cater the problem.

The results with management oversight board (MONITOR1) indicate that the proportion of non-independent non-executive directors (NINE) is found to have a significant and positive relationship with management oversight roles (MONITOR1) ($p<.05$). This suggests the importance of non-independent non-executive directors (NINE) to undertake greater management oversight roles. Managerial ownership (MOWN) is found to be significantly related to management oversight roles (MONITOR1) ($p<.10$) which suggests that when managers are holding higher percentage of ownership in a company, greater management oversight roles are conducted to protect managers' interests as higher percentage of ownership would align managers' interests with the shareholders' interests. Multiple directorships (MMDIR), board process, and board tenure are shown not significantly related to management oversight roles (MONITOR1). For control variable, it is found that larger companies are associated with higher management oversight roles. Independent board leadership (BLEAD) is negatively related to management oversight roles ($p<.05$). The significant relationship with

management oversight board suggests that CEO duality is significantly related to increased management oversight roles as a check and balance on the CEO decision making activities.

For the relationship between corporate governance and evaluation of managers' performance (MONITOR2), the results show the proportion of non-independent non-executive directors (NINE) is positively related to MONITOR2 ($p<.05$). Managerial ownership (MOWN) is found significant and positively associated with MONITOR2 ($p<.01$). Board size (BSIZE), board leadership (BLEAD), multiple directorships (MMDIR), percentage of meetings attendance (PMEET) and board's tenure (LGTEN) are not significantly related to MONITOR2.

Relationship between Corporate Governance and Strategy Roles and Service Roles

Refer to Table 8 - Regression Analysis between Corporate Governance and Strategy Roles

Regression analysis with strategy roles shows that board size (BSIZE) is significantly related to strategy role but in a negative direction ($p<.10$). The result is similar to those of Carpenter and Westphal (2001) and Ruigrok et al. (2006), which highlight that small board size is effective in strategic decision making. The proportion of non-independent non-executive directors (NINE) is positively related to strategy role ($p<.05$). Multiple directorships (MMDIR) have a negative relationship to strategy ($p<.01$). The result highlights the concern of having directors with multiple directorships (Haniffa & Coke, 2002) since it shows that having directors with multiple directorships are detrimental to strategic roles. The result is consistent with that of Carpenter and Wesphal (2001) and Ruigrok et al. (2006). Managerial ownership (MOWN) is significantly related with positive directions ($p<.01$). The result suggests the benefits of having high level of MOWN for the

703

strategic roles performed by the BODs. Other variables such as independent board leadership (BLEAD), percentage of meetings attendance (PMEET) and board's tenure (LGTEN) are not significant. The insignificant finding between board leadership and strategy role contradicts the findings of Muth and Donaldson (2005) and Ruigrok et al. (2006) who found CEO duality leads to higher strategy roles. For control variable, it is found large companies are associated with greater strategic roles.

Regression analysis with service roles shows that firm size (LGTA) is positively related to service roles ($p<.05$). This suggests that larger companies require greater services from their board of directors to create good company's reputation with the outside parties. Managerial ownership (MOWN) has strong influence on the level of services provided by the BOD as shown by the significant and positive relationships ($p<.01$). This supports the need for high level of MOWN for service roles. Other variables are not significantly related to service roles.

Relationship between Corporate Governance and Resource Dependency Roles

Standard and robust regression analyses were also conducted between corporate governance variables and other board performance dimensions (REDEP1 and REDEP2), however, the F tests for both models are not significant. However, after examining closely individual variables in the robust regression analyses between corporate governance and protecting shareholders' and other stakeholders' interests (REDEP1), it is found that independent board leadership (BLEAD) is significantly and negatively related to REDEP1 ($p<.01$). For the relationship with providing resources to management (REDEP2), firm size (LGTA) is found positively related to REDEP2 ($p<.01$). Other corporate governance variables are not significantly related to the roles of providing resources to management. The insignificant relationship with resource

dependency roles contradicts Wan and Ong's (2005) finding who suggest BOD as resource actors.

Conclusion

The study highlights some internal corporate governance mechanisms (i.e. board leadership, non-independent non-executive directors, multiple directorships, managerial ownership) which are found to be significantly related to greater board performance. The results support the importance of having non-independent non-executive directors as effective monitoring mechanisms and as facilitators in strategic planning and directions (Roberts et al., 2005). This finding suggests that non-independent non-executive directors have relevant incentives (represent blockholders and/or have significant shareholdings in the company) to monitor management decisions and provide strategic facilitation to the management and the board (Roberts et al., 2005). The positive relationship of non-independent non-executive directors supports the argument of Klien (1998) and Roberts et al. (2005) of the possibility of increased involvement in board functioning.

In relation to multiple directorships, the results of this study have practical implications to the current practices which allow directors to have up to 25 directorships (10 for public companies and 15 for non-public companies). The negative relationship between multiple directorships and strategy roles highlight the serious concern of multiple directorships in the Malaysian public listed companies. The findings also indicate the positive contribution of managerial ownership to improved board performance. Managerial ownership is proven to be as one of the incentive mechanisms for managers to work in line with shareholders' interests.

The negative relationship between independent board leadership and board performance is inconsistent with the potential of independent board leadership to board functioning. The insignificant findings of board knowledge and board process are

inconsistent with the revised code of corporate governance of having directors with high skills and experience and having more meetings. The insignificant may be due to those reputational directors are busy with other commitment as their expert may be required by other companies.

The limitation of the study is that the sample of the study only focuses on the main board companies. Thus, the findings of the study may not be generalized to other second board and MESDAQ companies. Further researches should be conducted in other boards (second board, MESDAQ, etc.) to determine whether the survey (instruments for board roles) holds in other boards.

Further researches should be conducted on multiple directorships as limited knowledge is available on multiple directorships status in Malaysia. Further studies may be conducted on determining the optimum multiple directorships for each type of directors such as executive directors and outside directors.

The positive relationships between non-independent non-executive directors with most of board performance dimensions in this study have potential impact on corporate governance practices. Further studies should be conducted on different settings and issues to see whether the findings hold.

APPENDIX

Table 1
Theoretical Perspectives on Board of Directors' Roles

	Legalistic	Agency Theory	Resource Dependence	Stewardship
Board role	• Representing and protecting shareholders' interest • Managing the corporation without interference in day-to-day operation	• The primary role of boards is to monitor actions of agents (executives) to ensure their efficiency and to protect principals (owners) interests	• Boards are co-optative mechanism to extract resources vital to company performance • Boards serve a boundary spanning role • Boards enhance organizational legitimacy	• Boards ensure the stewardship of corporate assets
Operational definition of boards' role	• Selecting CEO • Monitoring CEO performance • Representing shareholders' interests • Evaluating company performance	• Maximizing shareholders' wealth • Reducing agency cost • Selecting CEO and company performance CEO • Evaluating CEO and company performance • Strategic decision making and control	• Scanning the environment • Representing the firm in the community • Securing valuable resources	• Defining company objectives / setting corporate direction • Setting vision and mission • Formulating strategy • Setting ethical tone • Involving in risk management activities
Theoretical Origins	Corporate law	Economics & Finance	Organizational theory & Sociology	Organizational theory

RELATIONSHIP BETWEEN DIRECTORS' BONUS AND SHAREHOLDERS' VALUE:

A VIEW FROM CORPORATE GOVERNANCE

Akhma Adlin Khalid, Telekom Malaysia Berhad

Zubaidah Zainal Abidin, MARA University of Technology

ABSTRACT

Directors' remuneration research has traditionally focused on total salary, cash compensation and long – term incentives plans. Consequently, a systematic study on short – term annual bonus is lacking. To address this omission, this study is conducted to investigate the trend of bonus received by the executive directors among Malaysian companies publicly listed on Bursa Malaysia in the current economic condition from 2004 to 2006. The study also examines the relationship between the executive directors' bonus and shareholders value, specifically defined by firm performance, as measured using stock return and earning per share and by firm size, as measured using the total number of employee, so as to test the practice of the principle corporate governance among the Malaysian listed companies from two different theories, i.e. agency theory and power theory. For firm performance, the findings support the agency theory since directors' bonus is found to be positively associated with firm performance, as measured by EPS. However, the findings found no significant relationship between directors' bonus and stock return. For firm size, the findings support both theories since directors' bonus is found to be positively associated with firm size as measured by total sales and negatively associated with firm size as

measured by total number of employee. Consistent with the previous studies on executive bonuses, this association remains weak. However, power theory revealed that weak governance may foster the rise of powerful directors and thus, weaken the corporate governance value in a company. Therefore, it is suggested that close monitoring of directors' remuneration should continue and shareholders should remain extra vigilant.

Introduction

Many studies have been conducted to investigate the relationship between directors' remuneration and firms' performance (see for example Conyon and Leech, 1994; Conyon and Sadler, 2001; Ibrahim et al., 2005; Abdul Rahman and Mohd Zawawi, 2005). Indirectly, firms' performance seems to be the most likely capacity to measure shareholders value.   Some of the researchers claim that there is no significant relationship between directors' remuneration and firm performance (Ibrahim et al., 2005; Abdul Rahman and Mohd Zawawi, 2005). According to Conyon and Leech (1994), public concern has been expressed that the compensation packages received by those at the head of the corporation are not justified by the underlying economic performance of the company. Hence, this study took one step ahead to explore one

neglected element of directors' remuneration i.e. annual bonus in examining the relationship between directors' bonus and shareholders' value in Malaysia.

One recent study solely on annual bonus is done by Jay Daniel Fattorusso (2006) for the award of Doctor of Philosophy at Loughborough University titled, 'UK Executive Pay: The Special Case of Executive Bonus'. The results of the study demonstrated that there is a positive association between bonus pay and firm performance, both using internal and external measurement; i.e. earnings per share (EPS) and total shareholders return (TSR), respectively by using the a*gency theory* approach to reflect the principal and agent connectivity. In addition, the study further explores the relationship from the *power theory (self-serving management* approach) as to cater the complexity of the different interests in ownership types. This resulted that bonus pay is negatively associated with firm performance from the *power theory* approach. On top of that, Fattorusso (2006) also discussed on the relationship between executive bonus and firm size, as an extended view of firm performance from both approach mentioned earlier. The result is that bonus pay and firm size is not positively associated from the agency theory perception while it is positively associated from the power theory point of view.

On this note, it is crucial to investigate the relationship between directors bonus, being part of an important element in the directors remuneration and the shareholders' value represented by firms' performance and firms' size in the current economic condition on

the fact that the stability of corporate governance being practiced by most of the companies in Malaysia as compared to the time when corporate governance was at initial stage back in year 2000. Hence, based on sample of 74 (from the total of 545 observations) companies listed on the Bursa Malaysia, this study investigates the relationship between directors' bonus and shareholders value of the Malaysian listed companies for the year 2004 until the year 2006. The said period is deemed to be an appropriate period of study on the basis of readily available information and familiarity in the subject of corporate governance amongst the listed companies in Malaysia. For the purpose of the study, the sample is selected from the listed companies in all main industries on the Main Board of Bursa Malaysia. Directors' remuneration is further delved into directors' bonus portion while shareholders value, which is represented by firms' performance, are measured using stock return (SR) and earnings per share (EPS) and firms' size, are measured using total number of employee and total sales.

This study is not only significant to ascertain the relationship between the directors' bonus and shareholders' value, but further to reveal what are the patterns of the bonus received by the executive directors for Malaysian listed companies in the current economic condition. The most important is to discover whether the board of directors is mindful of enhancing shareholders value, a cornerstone of corporate governance by implementing agency theory approach or they are is mindful of enhancing their own wealth, as argued by the power theory. The findings from this study will contribute to

the literature on the correlation or relationship between directors' bonus and firms' performance as well as firms' size, which indirectly represent the shareholders value.

Agency theory

The idea of agency theory has been long discussed by scholars in various field specifically accounting (for example Garen, 1994; McColgan, 2001). In fact, literatures on agency theory has been explored during the 1960s and 1970s describing the risk – sharing problem as one that arises when cooperating parties have different attitudes toward risk (Eisenhardt, 1989). Subsequently, agency theory had broaden this risk – sharing concepts by including the '*agency problem*' that occurs when the cooperating parties have different goals.

Jensen and Meckling (1976) in its article mentioned that the concern of agency theory lies in the incentive problems that arise when the decision making in a firm falls within the province of managers who are not the firm's security holders.   Given a various version of agency theory's definition mentioned above, it is well understood that the principal or shareholders are given no option than partly (to some extend, mostly) delegate the decision making process to the agents or directors who run the company despite of the divergence desires and risk – attitude between them., i.e. *agency conflicts*.

Agency theory is also best explained in the form of corporate governance. This is because the theory holds that managers will not act to maximize the returns to shareholders unless appropriate governance structures are implemented as a mechanism to safeguard the interests of shareholders (Donaldson and Davis, 2001). Furthermore, the definition of corporate governance suggested by the High Level Finance Committee Report on Corporate Governance (1999) has obviously implies the similar direction with agency theory. This is supported by McDonald et al. (2008) that corporate governance factors can also be employed to remedy the agency problem, at least in part and thereby reduce the agency costs to increase the alignment of managers' personal interest with the core interest of shareholders.

Power theory

Power theory emphasize on the fundamental misalignment of interests between the principal and the agent (Fattorusso, 2006). From the word 'power theory' itself, it is understood that the managerial power is heavily associated with the separation of ownership, that refers to a situation where power and control of the corporation has been shifted away from the common stockholders (Fattorusso, 2006).

Meanwhile, *power* refers to the ability of an individual to influence others and affect their behaviour (Isabella, 1992). However, the managerial power perspective does not assume that directors seek to get the best deal for shareholders (Bebchuk and Grinstein, 2005). This is because power can also be abused when executives are self –

serving and being opportunistic towards the undaunted power given by the shareholders. Additionally, management may pursue its own interest obliviously to the welfare of the owners (Werner and Tosi, 1995).

Due to the above, by having most of the power lies with the directors, it is important that the shareholders have the power in the company as well. Shareholder power is supposed to supply a critical safety valve that prevents directors from straying shareholders' interest (Bebchuk, 2003). For example, should the shareholders are not satisfied with the action of their elected representatives, they have the power to turn the board out. As a result, power plays a central role in various aspect of corporate governance. This is proven by Finkelstein and D'Aveni (1994) who discussed on the managerial power and how it is dependent with the ownership structure of the firm, the board composition as well as its duality.

Directors' Remuneration and Firm Performance

Studies on correlation of personal returns received by directors to the returns received by shareholders have been extensively discussed by the Western researchers especially in the states and United Kingdom. Much debate in these countries revolves around the linkage of directors' remuneration and firms' performance from various researchers' perspectives in defining directors' remuneration as well as firms' performance. No matter how diversify the arguments are, the result of the discussion is biased towards the existence of the relationship between directors' remuneration and

firms' performance at a very small substance (see for example Conyon, Gregg and Machin, 1995).

Jensen and Murphy (1990) prove that there is positive relation between cash compensation and firm performance in a well known study on 2,213 CEOs in United States for the period from 1974 – 1986. Researchers in United Kingdom too found a very small sensitivity between directors' remuneration and firms' performance. In the same vein, the issue on relationship between directors' remuneration and firms' performance does receive much attention in other countries than US and UK since the interest on directors' compensation is a world – wide surge that investors, analysts, policy makers, journalist and public are always keen on. However, less research has been conducted in other countries due to the disclosure on directors' remuneration that do not go far enough in those countries (Kabir, 2008).

In the Malaysian context, Dogan and Smyth (2002) have made an attempt to fill the gap in the Asian literature, by a research conducted on the determinants of board compensation in Malaysian firms listed on the Kuala Lumpur Stock Exchange over the period of 1989 – 2000. Dogan and Smyth (2002) however found that directors' remuneration is positively correlated with stock market performance but negatively correlated with accounting measures.

On top of that, Ibrahim et al. (2006) has further explored the relationship between directors' compensation and firms' performance among companies in Malaysia using data from 1999 to 2001. The study intends to see the relationship subsequent to the announcement of the new ruling on corporate governance by Kuala Lumpur Stock Exchange in 2000 which was predicted to be stronger in 2001 as compared to pre-implementation period. However, the findings show that there is a non – significant relationship between pay and performance in 2001 and instead Malaysian companies tend to link directors' remuneration with growth and size rather than performance.

Bonus – based incentives

There has been little research that split directors' remuneration between base salary and bonus. One of the obvious reasons is because both were rarely broken down separately. Veliyath (1999) has defined salary as cash compensation that is determined at the beginning of an annual pay cycle, while annual bonus is defined as cash compensation that is determined at the end of an annual pay cycle and is based on only one – year's worth of performance information. Hence, annual bonus seems to be an important component in directors' remuneration as it reflects short – term performance of a company (for example Holthausen, 1995; Fattorusso, 2006).

Subsequent to the corporate scandals i.e. Enron, WorldCom that relates to proliferation of stock options in the CEO pay, bonuses are likely to become an even more important component of CEO compensation (Sheikh, 2008). Studies that specifically examine the

executive bonuses were found to be positively, though weakly associated with shareholders' value and thus, no evidence of bonus being a purely manager – serving device (Bruce et al., 2007). However, the result is in contrast with Healy (1985) who concluded that bonus schemes create incentives for managers to select accounting procedures and accruals to maximize the value of their bonus awards.

Value of the annual bonus and firm performance

Agency theory is based on the premise that principal (shareholders) delegate duties to the agent (the board and CEO) who is expected to act in the best interest of the shareholders. As such, it is the boards' responsibility to design compensation schemes that provide managers with efficient incentives towards maximizing shareholders' value (Bebchuk, 2003). Hence, based on the empirical evidence from those studies, agency theory assumed that the board will design bonus schemes based on performance targets that contribute to the shareholders wealth.

Existing literatures that exclusively examine the short – term annual bonus and firm performance include Bushman et al. (1995), McKnight (1996), Fattorusso (2006) and Bruce et al. (2007). For example, Bushman et al. (1995) found that 33.7% of the average division CEO's annual bonus in 246 public domestic firms in the states is based on group level or corporate level performance measures. Similar relationship was found in Fattorusso's (2006) study that supports the agency theory view as the bonus amount is positively associated with financial performance, both measured using

EPS and TSR. Hence, the first hypothesis for the study under the agency theory is as follow:

H$_{1a}$: The value of directors' bonus is positively associated with firm performance, as measured by stock return and EPS.

As for the power theory, the conflict of interest between principal and agent is due to the self – serving executives, who are opportunistic and will participate in dysfunctional behaviour when given necessary latitude (Conyon and Sadler, 2001; Fattorusso, 2006). Moreover, since ownership and control has become more dispersed due to the separation of control between shareholders and executives, power theory suggest that executives are able to fully entrench themselves in the entire company and extract greater rents through their compensation arrangements and oblivious to the welfare of the owners (Bebchuk and Fried, 2004). In addition, Choi (2008) comments that as CEO's power become stronger, they may be free to undertake excessively high risks project for personal gain, potential resulting in large losses for the firm. Hence, it is assumed that under this theory, the following hypothesis is as follows:

H$_{1b}$: The value of directors' bonus is negatively associated with firm performance, as measured by stock return and EPS.

Value of the annual bonus and firm size

Although the relationship between directors' compensation and firm size has less attention as compared to firm performance, there are many researches conducted on this which started in the past five decades ago (for example McGuire et al., 1962; Lewellen and Huntsman, 1970). Using more current evidence, Bebchuk and Grinstein (2005) found an interesting evidence that the firm size increase is followed by higher CEO pay but firm size decrease is not followed by lower CEO pay.

This implies that firm size expansion is not motivated by maximization of shareholder wealth but is associated with CEO compensation increases (Bebchuk and Grinstein,2005). However, there is not much attention that focuses specifically on directors' bonus with firm size. Due to the limited literature, researches that concluded on directors' compensation (cash compensation) and firm size are being considered to develop the hypothesis.

Studies that specifically examine the relationship between directors' compensation and firm size include McGuire et al. (1962), Tosi et al. (2000) and Ibrahim et al. (2006). Most of the studies use total sales, market value, net assets and number of employee as a measure of firm size. However, the High Level Finance Committee Report on Corporate Governance (1999) states that executives are expected to maximize the shareholders' value through raising a company's share price, which is consistent with the agency theory. As such, strategies to increase firm size that were considered to be

non-maximising would be avoided as a course of action (Fattorusso, 2006). Consequently, this has led to the following hypothesis:

H_{2a} : The value of directors' bonus is negatively associated with firm size, as measured by total number of employee and total sales.

Power theory, on the other hand has the mirror image of this hypothesis on the argument that directors who posses self – serving management behaviour will focus on self – interested objectives rather than the shareholders. Generally, the relationship between directors' compensation and firm size supports power theory as it is less sensitive to performance and more sensitive to firm – size expansion (Choi, 2008). Therefore, directors under power theory are more incline to grow the firm size rather than stock return and EPS. This may be due to the positive affirmations associated with running large corporations (Fattorusso, 2006). Consequently, it is hypothesized as below:

H_{2b} : The value of directors' bonus is positively associated with firm size, as measured by total number of employee and total sales.

Based on the above literatures, the conceptual framework of relationship between directors' bonus and shareholders value are summarize in the following figure:

Figure 1: Conceptual Framework of Relationship between Directors' Bonus and Shareholders' Value

Sample Selection and Data Collection

The companies included in the sample are drawn from all main industries listed on all boards of Bursa Malaysia. This contradicts Ibrahim et al. (2006) who excluded all financial companies listed at Bursa Malaysia. However, there are also considerably numbers of studies that do not exclude the finance sectors as part of the sample in addressing the same issue (for example, Tosi et al., 2000; Fattorusso, 2006). The sample selection from 8 main industries namely consumer products, industrial products,

construction, trading or services, properties, plantation, technology and finance is important to reflect the Malaysian emerging capital market as a whole.[84]

Besides, the sample must have all required accounting data, shares price and total number of employees that are available for the year 2004 until the year 2006 to estimate the relationship between directors' bonus and shareholders value as used by Fattorusso (2006). The said period is deemed to be appropriate on the basis of familiarity and awareness on corporate governance amongst the listed companies in Malaysia.

Only secondary data are needed for this study and the data including the stock prices, EPS, total number of employee and total sales are collected from DataStream International which is a comprehensive database containing financial information of companies listed on exchanges and over the world. For the purpose of this study, companies that separately disclosed their directors' bonuses amounts are selected and the data are specifically extracted from companies' audited report available in the Bursa Malaysia website. Companies with incomplete data are excluded.

After taking into consideration on all the sample selection criteria, a total of 74 companies become the final sample used for the study. In addition, the samples are

---

[84] Industry classifications were based on the Bursa Malaysia categorization taken from

http://www.bursamalysia.com

further corroborated with the samples of companies in the joint survey between the Minority Shareholder Watchdog Group (MSWG) and University Teknologi Mara namely, "Directors' Remuneration Survey" done in 2007 to enhance the value. This is because the survey was performed on the top 500 PLCs based on market capitalization as at 31 December 2005. Due to a small sample size used in this study as compared to previous studies on these issues, the result of these findings is more appropriate to represent the companies within the sample instead of generalizing it to represent the public listed companies in Malaysia.

Measurement of Variables

Dependent Variable

Information on total directors' remuneration is clearly detailed in a firm's financial statements. However, information specifically on annual bonus required considerably more time to decipher, primarily because of the confusion surrounding when earned annual bonuses were actually reported as paid (Knight, 1996). This is because some firms reported annual bonuses in the year paid (i.e. subsequent year) rather than in the year ended (i.e. current year) and this represents a potential timing problem (Knight, 1996). For the purpose of this study, the bonus amount stated in the audited report is considered current unless it mentioned otherwise.

In most of the financial statements of public listed companies in Malaysia, the annual bonus information is normally form part of the 'other short – term benefit' such as

directors' fee, emolument, allowances and estimated monetary amount of benefits – in – kind rather than to be presented individually as directors' bonuses. In fact, there are a great number of financial statements that lump the bonus figures with the basic salary as part of the directors remuneration. Using the sample employed by the Directors' Remuneration Survey in 2007 by MSWG and UiTM, the number of companies that lump the bonus figure is 447 (89%) leaving the remaining 11% of companies that are included in this study's sample size. Apparently, this might be the main reason for a limited data in this study.

As such, extracting the particular bonus amount from the annual reports of all companies listed in the Bursa Malaysia for the three years period from 2004 to 2006 is meticulous, thus requires extra cautious. Since bonus is the distinctive value in this study, any vague information in the financial statements on directors' bonuses will be excluded from the sample. Bonus with nil amounts during the year will still be included in this study.

Independent Variable

For independent variables, shareholders value will be detailed explained in two perspectives, i.e. firms' performance and firms' size. Firms' performance will be operationalised as stock return and EPS while firms' size will be measured using total number of employee and total sales at the end of each financial year from 2004 to

2006. All four independent variables used in this study are taken from the companies' financial statements.

Stock performance is usually measured by the changes in stock price (Attaway, 2000). Benito and Conyon (1999) and Tosi et al. (2000) have used stock performance to measure the performance of firms' stock in their respective studies while McKnight (1996) employs shareholder return in his study. For the purpose of this study, the variable used is consistent with Firth et al. (1996) i.e. stock return at the end of each financial year. Stock return is computed as changes in stock price (adjusted for capital changes) plus dividend per share.

This study further adopted EPS as a second independent variables to measure the firms' performance from the accounting – based measurement. EPS is widely used (for example Randoy and Nielsen, 2002) in evaluating the operation performance and profitability of a company to justify the directors' compensation as it is a fair reflection of a firm's internal performance (Fattorusso, 2006). Basic EPS is computed using net income divided by the number of shares outstanding during the year.

Roberts (1956) in Fattorusso (2006) mentioned that despite using net sales as the index of corporate size, other measures of corporate size did not alter his conclusion significantly. Due to that, the third independent variable adopted in the study is the total number of employee stands at the end of each fiscal year for all companies listed in

Bursa Malaysia from 2004 to 2006. This is inline with Tosi et al. (2000) who propose that size has been operationalised by firm sales, the square root of sales, the log of sales, the number of employees, total assets and log of total assets. The number of employee considers all staff, including directors and other top management executives within the company.

The study employs total sales, as the fourth independent variables use as an alternate measurement for firm size. This is because total sales have been widely used as to represent the firm size. McGuire et al. (1962) have used the revenue figure to determine the relationship between executive incomes, sales and profit. In more recent studies, McKnight (1996) also uses total sales to represent firm size in providing the explanation of top executive pay in UK. Hence, it is crucial to expand Fattorusso's (2006) study by including total sales as an additional independent variable to measure firm size in order to increase the reliability of the study.

Finally, this study employs leverage ratio to be a control variable in examining the relationship between all the independent variables and directors' bonus. This is similar with Duffhues and Kabir (2008) who assumed that companies with higher debt will be closely monitored by the creditors or debt holders. Hence, the companies thereby reduce the payment of any excess compensation to the directors. Apart of that, higher debts lead to high risk which necessitates the payment of higher compensation (Duffhues and Kabir, 2008). Leverage ratio is defined as total debt over total assets.

Result and Discussion for Hypotheses Tests

Descriptive Statistics of Dependent Variables

Table 1 presents the descriptive analysis for annual bonus received by the directors of companies traded in Bursa Malaysia for the period from 2004 to 2006. From the table, it is noticed that the highest and lowest annual bonus received by Malaysian directors among the public listed companies (within the samples selected) for the period between 2004 to 2006 are RM6,939,000 and RM5,000 respectively, both in year of 2006.

Despite of that, it is also noticed that the average level of bonus received by directors decreased from RM411,292 in 2004 to RM370,790 in 2005 and subsequently followed by an increased to RM516,198 in 2006, evidenced by the mean amount presented in Table 1. Accordingly, the bonus growth in 2005 of -10% has sharply increased to 39% in the 2006 bonus. McKnight (1996) too, found that the bonus growth from 1993 to 1994 grew at astonishingly rate of 18.32% in his 3 years study from 1992 to 1994. Accordingly, the median bonus amount for this study also fluctuates by RM15,000 in 2005 and subsequently increased by RM53,000 in 2006. This seems to contradict Fattorusso (2006) who found that the median bonus figure rose by 30% (£37,000) over the 2 year period from 2001 to 2003 among the FTSE 350 companies in the UK.

Table 1: Descriptive statistics for annual bonus by year

Year	N	Mean	Median	Std Dev	Min	Max
2004	66	411,292	164,975	712,059	9,000	4,098,000
2005	73	370,790	150,000	674,005	10,833	5,062,000
2006	71	516,198	203,150	1,001,032	5,000	6,939,000

Test of normality

Test of normality is performed in order to determine the most appropriate statistical tool to be used in the correlation analysis. Therefore, the result from the normality test is presented in Table 2.

Table 2: Test of Normality on variables values

Variables	Normal parameters	Most extreme differences		Kolmogorov – Smirnov Z	Asymp. Sig. (2-tailed)
	Mean	Positive	Negative		
$BONUS_{log}$	12.12	0.060	-0.048	0.517	0.952*
SR	0.15	0.117	-0.060	1.004	0.266*
EPS	0.16	0.118	-0.124	1.063	0.208*
$E'EE_{log}$	6.89	0.089	-0.076	0.768	0.597*
$SALES_{log}$	12.81	0.116	-0.062	0.996	0.275*
LEV	0.42	0.115	-0.058	0.993	0.277*

* Significant at the 0.01 level

Table 2 shows the result of the One – Sample Kolmogorov-Smirnov Z normality test on all values used in the study. Hence, it is observed that all variables used are normally distributed based on the fact that $p > 0.01$. Apparently, variables which are not normally distributed have been transformed into log (similar with Conyon, 1995) using SPSS12.0. Variables that have been transformed into log are bonus, total number of employee and total sales. Due to that, Pearson correlation analysis, a parametric statistical tool is used to examine the relationship between the directors' remuneration,

i.e. BONUS$_{log}$ and the shareholders value, i.e firm performance, measured by SR and

EPS and firm size, measured by E'EE$_{log}$ and SALES$_{log}$.

Correlation Analysis

The results of the correlation analysis are shown in Table 3.

Table 3: Pearson correlation between directors' bonus and shareholders value

		Log bonus (BONUS$_{log}$)	Stock return (SR)	Earning per share (EPS)	Log total number of employee (E'EE$_{log}$)	Log total sales (SALES$_{log}$)
Pearson Correlation	BONUS$_{log}$	1.000	.233	.419	.337	.527
	SR	.233	1.000	.323	.319	.399
	EPS	.419	.323	1.000	.581	.636
	E'EE$_{log}$	.337	.319	.581	1.000	.783
	SALES$_{log}$	.527	.399	.636	.783	1.000
Sig. (2-tailed)	BONUS$_{log}$	.	.046	.000	.003	.000
	SR	.046	.	.005	.006	.000
	EPS	.000	.005	.	.000	.000
	E'EE$_{log}$	.003	.006	.000	.	.000
	SALES$_{log}$	.000	.000	.000	.000	.
N	BONUS$_{log}$	74	74	74	74	74
	SR	74	74	74	74	74
	EPS	74	74	74	74	74
	E'EE$_{log}$	74	74	74	74	74
	SALES$_{log}$	74	74	74	74	74

Based on Table 3, there is a positive and significant (Sig. value = 0.046) though weak

(r = 0.233) relationship between directors' bonus and stock return. For EPS, there is

also a positive and significant relationship between directors' bonus and EPS. However,

the strength of relationship between these variables is moderate as compared to stock

return, based on the coefficient of correlation value of 0.419. Relationship between

directors' bonus and firm size, measured is found to be significant at any level of confidence (2-tailed), as evidenced by the Sig. value in the table above. However, the result shows that total sales are more correlated to directors' bonus based on the coefficient r value of 0.527 as compared to total number of employee (coefficient r value = 0.337).

Multiple Regressions Analysis

The hypotheses developed in the study is to explore whether there is any relationship between directors' bonus and shareholders' value variables. Once the relationships have been identified, regression analysis is used to explore the relationship in depth.

The relationship is expressed as an equation that predicts the dependent variable from a function of the independent variables (regressors) and a set of constants called the parameter. For the purpose of this study, the dependent variable is log directors' bonus ($BONUS_{log}$) and the independent variables are stock return (SR), earning per share (EPS), log total number of employee ($E'EE_{log}$), log total sales ($SALES_{log}$) and leverage ratio (LEV). Hence, the multiple regression equation model is as follows:

$$BONUS_{log} = \beta_0 + \beta_1\,SR + \beta_2\,EPS + \beta_3\,E'EE_{log} + \beta_4\,SALES_{log} + \beta_5\,LEV + e$$

As all variables are normally distributed, regression analysis can be properly executed. On top of that, several tests for autocorrelation and collinearity are also carried out.

Hence, Durbin – Watson test, one form of test for autocorrelation is used to check for autocorrelation, a condition in which a relationship exists between consecutive residuals (similar with Abdul Rahman and Zawawi, 2005).

The test indicates that there is no evidence of autocorrelation since the Durbin – Watson coefficient is 1.691 and it lies within the range of 1.69 and 2.31. Thus, there is no time effect of the performance of the companies on the directors' bonus over the observed period, i.e. 2004 to 2006. Furthermore, high tolerance levels (i.e. significantly different from zero) suggest that collinearity or multicollinearity is unlikely, based on the data shown in Table 4 below. Collinearity (or multicollinearity) is the undesirable situation where the correlations among the independent variables are strong.

Table 4: Multiple Regression Analysis Result

	Unstandardized coefficients		Standardized coefficients			Collinearity Statistics	
	B	Std. Error	Beta	t	Sig.	Tolerance	VIF
(Constant)	6.679	1.529		4.367	.000		
SR	.058	.476	.013	.122	.903	.828	1.207
EPS	1.068	.879	.170	1.215	.229	.515	1.941

a. Predictors: Leverage ratio, EPS, stock return, log total no of employee and log total sales

Table 4 contains the coefficient of determination (R-Square) that measures the degree of predictive accuracy of the regression model in explaining the variations in the

dependent variable, i.e. directors' bonus. As such, it is noticed that the model explains 31% of the variation in directors' bonus based on the R-Square value. This means that there are other variable (69%) which are not included in the model are also related to directors' bonus. Furthermore, due to the small number of sample size in the study, it is believed that the regression result does not accurately represent the entire population of public listed companies. However, the sig. value of 0.000 < 0.01 shows that there is enough evidence to reject the null hypothesis at the 1% level of significance or higher. Hence, the regression model used in this study is significant and can thus, be used to explain or predict the bonus amount received by the Malaysian directors among the public listed companies within the sample selected.

In addition, the table shows that total sales seem to be the only factor that is significant to predict directors' bonus as proved by the sig. value of 0.002. This implies that there is also enough evidence to reject null hypothesis at 1% level of confidence of higher. However, the remaining variables show slight or no significant effect to the variation of directors' bonus. Surprisingly, the leverage ratio being the control variable in this model also has no significant influence to directors' bonus.

Directors' Bonus and Firm Performance

Looking back to the hypotheses, **H$_{1a}$** states that the value of directors' bonus is positively related to firm performance under the agency theory. In order to have a

better discussion, our findings are separated into stock return and EPS in its respective paragraph as follows:

Based on the Sig. value of 0.903 in Table 4, we **accept the null hypothesis** since there is no significant relationship between directors' bonus and stock return. This finding seems to be consistent with some of the earlier studies conducted on directors remuneration (cash compensation) due to limited studies specifically done on directors' bonus. The study is supported by Greg et al. (1993) who initially found a weak correlation between directors' compensation and stock market valuation over the period of 1983 – 1988 but the link subsequently disappear over the period of 1989 - 1991. On top of that, Dogan and Smyth (2002) suggested that the relationship between board remuneration and firm performance is ambiguous in Malaysia, over a study period between 1989 to 2000.

For EPS, the study found a positive relationship between EPS and directors' bonus. This is consistent with McKnight (1996) who found a positive and statistically significant relationship between changes in EPS and changes in annual bonuses for the sample throughout 1992 – 1994 in UK. On the contrary, Randoy and Nielsen (2002) found no significant relationship between CEOs' compensation and EPS in 224 companies from Norway and Sweden within the period from 1996 to 1998.

Due to the above, our results for both firm performance measures, i.e. stock return and EPS provide partial support for H_{1a} which states that the value of directors' bonus is positively related to firm performance, as measured by stock return and EPS under the agency theory. This is because H_{1a}, is accepted when firm performance is measured using EPS but null hypothesis is accepted when firm performance is measured using stock return. Since our result for firm performance seems to partly accept the H_{1a}, by implication the study also partly reject H_{1b}.

Consequently, H_{1a} that states the value of directors' bonus is positively associated with firm performance, i.e. stock return and EPS under the agency theory is **partly accepted**. On a contradictive perspective, H_{1b} that states the value of directors' bonus is negatively associated with firm performance, under the power theory is therefore **partly rejected** as well. In other words, our results support agency theory when firm performance is measured using EPS while no significant pay – performance relationship was found in this study when firm performance is measured using stock return.

In overall, the result implies that Malaysian directors in the public listed companies (within the sample selected) are more transparent since our result shows a positive relationship between directors' bonus and EPS (accounting – based performance measure). This is because Jensen and Murphy (1990) states that positive sign of

accounting base performance may yield information that is valuable in assessing an executive's unobservable actions.

Directors' Bonus and Firm Size

Common sense would tell us that larger firms normally give higher compensation. This general argument seems to be inconsistent with our third hypothesis, H_{2a} which states that the value of directors' bonus is negatively associated with firm size, as measured by total number of employee and total sales under the power theory. For a better discussion of result, total number of employees and total sales are separately discussed according to the respective paragraph as follows:

The study found a negative relationship between directors' bonus and total number of employee. As such, our result contradicts Fattorusso (2006) who suggested that firm size, as measured by number of employees is weakly but positively related with bonus pay. Apart of that, the finding generally does not agree with the assumption that bigger companies which have complex responsibilities tend to pay more to their directors due to the fact that more complex and demanding tasks (Ibrahim et al., 2001).

Total sales, however is found to be positively significant in explaining directors' bonus. This is consistent with McKnight (1996) who found an eminently strong and positive association between annual bonus and total sales which proposed that a 10% larger firm (using total sales) will pay its executives on average 11.2% greater in bonus.

745

Perhaps, most of the public listed companies within the sample of the study strive to increase its sales as it has been said that increasing the volume of sales will achieve greater prestige and eventually lead to higher compensation (Murphy, 1985 and Ibrahim et al., 2001).

Under agency theory, any related effort to increase the firm size be it by the total number of employee or total sales is considered contradicting in maximizing the shareholders value. Therefore, our results for both firm size measures provide partial support for hypothesis H_{2a} which states that the value of directors' bonus is negatively related to firm size, as measured by total number of employees and total sales under the agency theory. This is because H_{2a}, is accepted when firm size is measured using total number of employees but it is rejected when firm size is measured using total sales. Since our result for firm size seems to partly accept the H_{2a}, by implication the study also partly accept H_{2b}.

Consequently, H_{2a} that states the value of directors' bonus is negatively associated with firm size, i.e. total number of employee and total sales under the agency theory is **partly accepted**. On a contradictive perspective, H_{2b} that states the value of directors' bonus is positively associated with firm size, i.e. total number of employee and total sales under the power theory is therefore **partly accepted** as well. In other words, our results support agency theory when firm size is measured using total number of employee while power theory is supported when firm size is measured using total sales.

Conclusions and Implications

The study performs descriptive, correlation and multiple regression analysis in order to achieve its objectives. The results from descriptive analysis show that trend of bonus received by the executive directors among Malaysian listed companies (within the sample size) during the period of study from 2004 to 2006 fluctuates as evidenced by the average value of bonus from RM411,000 in 2004 decrease to RM371,000 in 2005 and subsequently increased to RM516,000 in 2006.

The result from the regression analysis provides that directors' bonus is positively related to firms' performance as measured using EPS while no significant relationship is found between directors' bonus and stock return. On top of that, directors' bonus is also found to be positively related to firm size as measured by total sales and negatively related to firm size as measured by total number of employee.

Based on the overall findings summarized above, it is observed that principle of corporate governance, particularly on directors' remuneration as exclusively represented by the directors' bonus is being well practiced in the Malaysian context, particularly for the public listed companies that falls within the sample of the study during the period between 2004 to 2006. This is because the corporate governance which is consistent with agency theory seems to be proven by the findings of the study.

At the very least, it is too soon to conclude on the basis of prior research. However, two out of four variables in this study i.e. EPS and total number of employee support agency theory at best. Power theory, however is only supported by total sales while stock return do not support any of the theories due to no significant association with directors' bonus.

Even though the length of the study period is short and thus, provides a limited view on directors' bonus in Malaysia as a whole, it is believe that this study contributes to the existing knowledge on corporate governance, specifically in respect of directors' remuneration. Furthermore, this study has four characteristics that make it distinctive (replicated from Fattorusso, 2006).

First, many empirical studies on directors' remuneration conducted in the past utilized American and UK data. Therefore, due to a shortage of research on directors' remuneration that utilizes Malaysian evidence, the present study will focus on Malaysian context, specifically among companies that are publicly listed on Bursa Malaysia. Secondly, much of the past research on directors' remuneration has focused on aggregate pay measures. As a result, few, if any studies has analysed exclusively the relationship between bonus pay, as a single feature of directors' remuneration and shareholders' value, further defined as firms' performance and firms' size. Third, the data is current and based on three consecutive years, i.e. 2004 – 2006, that is after the grace period of five years from the year where The Committee carried out a study on

748

corporate governance and Malaysian Institute of Corporate Governance (MICG) was established, i.e. 1998. And finally, this study uses two prominent theories in the executive pay literature, i.e. agency theory and power theory, in order to explain the relationship between directors' bonus and shareholders value.

RISK RELEVANCE OF ACCOUNTING VARIABLES

Vida Mojtahedzadeh, Al-Zahra University

Rahele Homayouni Rad, Al-Zahra University

Abstract

The purpose of this study is to analyze the relationship between market risk and accounting variables for determining the relevant key accounting variables and the risk relevance of accounting information. In this regard, twelve accounting variables are selected and classified into operating risk (7 variables), financing risk (2 variables), and growth risk (3 variables). The statistical population includes the listed companies in TSE and a sample of 61 firms during the period 1997-2006. A multivariate regression is used to test hypotheses. The results indicate that there is no significant relationship between accounting variables and systematic risk.

Key words: operating risk, financing risk, growth risk,accounting variables

JEL Classification :G14,G30

Introduction

Investments are one of the basic and crucial elements of the economic growth and development process in every country. Investors try their best to invest their funds in ways that would yield the best return with lowest risk possible. One of the methods for calculating systematic risks of companies is to utilize accounting

information. Therefore it is of great significance to recognize the relationship between systematic risk and accounting information.

To predict net future cash flows, investors usually need information on timings and amounts, access to risk, and the appropriate rate of interest for discounting expected cash flows of the entity. Therefore, one of the basic information necessary for investors is the investment risk. Risk can be defined as the probability of a difference between real returns and expected returns (Jahankhani and Parsayian, 1997).

In financial literature, risk has been addressed from various aspects. According to one approach, risk can be classified into two categories. The first category, consist of risks related to internal factors within a company. These types of risks are unique to the company and are not related to risks within other companies; and may therefore be unique to an industry. This is called non-systematic risk (avoidable). The second category includes risks not related to one or more companies; but rather to the market in whole. These types of risks are created due to factors such as macro-economic indices; they influence the total market yield and are called systematic risks (unavoidable). This risk is defined as those fluctuations in the return on assets that relate to the simultaneous influences of several factors on the price of that asset (Brimble & Hodgson, 2002).

Risk management is one of the significant components of a guidance system within an entity. This is a subject addressed even by small companies with a not very diversified range of activities. Moreover, beta cannot be directly measured

through changes in stock price of companies not traded in the stock market, as a substitute for systematic risk. This creates certain problems in estimations of capital expenditures and the structure of risk in companies not traded in the stock market. Past researches reflect that accounting variables contain material information for measuring risks. Therefore testing accounting variables related to the measurement of systematic risk contains information content for investors and managers as a substitute for estimations made based on market information (Brimble & Hodgson, 2002).

Earlier, researches were performed on the relationship between risks and accounting information by Beaver, Kettler and Scholes (1970) in the United States and Castagna and Matolcsy (1987) in Australia; however much dispersion can be observed in the performance of these studies.

According to Ryan (1997), there are five stimuli for performing researches related to measuring systematic risk: (1) expansion of criteria for the measurement of incurred risk, (2) determining actual risk instead of risk levels, (3) resolving risk identification problems for companies not traded in the stock market, companies offering stocks to the market for the first time, and institutions with little commercial background, (4) reducing noise in estimations of risks based on historical return of securities, (5) expansion of trading solutions and the ideal composition of a portfolio with varying levels of risk. In fact accounting data are used as substitutes for security prices or adjustments of prices determined based on systematic risk.

The main objective of previous researches that have been performed in this field has been to discover key variables for risk assessment. Results of these researches have helped in proposing amendments to the rules governing financial disclosure; this ensures an appropriate level of disclosure, to stockholders, of a relative risk in financial information. This has therefore been useful in decision makings regarding the allocation of assets. To solve the problem of the inflexibility of historical cost based accounting systems, some researchers have initiated discussions on the expansion of a set of standards relating to accounting risk (Scholes, 1996; Ryan, 1997). According to them, accounting based on current values can offer more effective information to users to assist them in evaluating the company's risks (Ryan, 1997).

In this research, various methods have been used to expand earlier studies. First, accounting variables related to systematic risk based on the market model have been identified using coherency methods. These variables have been classified into three groups, namely operational, financing and growth risks. Secondly, aside from the Market model, indices such as certain factors within the company were used to illustrate the dynamic nature of risk with time. In this method, we analyzed whether or not accounting variables as identified in this study were able to adjust themselves to dynamic and changing environmental conditions.

History of Research

Systematic risk points out the variability of the company yield which is linked with the market factors and is not eliminated with diversification. The usual method used for the estimation of systematic risk is the Capital Assets Pricing Model (CAPM) which is also used for the calculation of the Beta moving average (Sharpe, 1964; Lintner, 1965). Therefore certain studies in the field of accounting have attempted to identify those accounting variables which can be related to the mentioned criterion for risk assessment. The key issue here is the role played by some of the accounting variables in determining systematic risk (Ryan, 1997; Laveren et. al., 1997). Upon determination of the variables, a model was presented that would link systematic risk with accounting variables in theory (Penman, 2001).

Ball and Brown (1969), have examined the relationship between systematic risk and accounting income. They have considered three types of income as variables: operational income, net income and stockholders' share of income. The statistical population consists of 261 companies listed in US Stock Exchange between 1946 and 1966. Data obtained have been analyzed through regression methods. Results have reflected a significant relationship between systematic risk and accounting variables.

Beaver, Kettler and Scholes (1970), have attempted to examine the relationship between market fluctuations and accounting variables. For this purpose, seven accounting variables have been chosen and their relationship with systematic

risk tested. These include dividends, asset growth, financial leverage, company size, current ratio, income standard deviation, and accounting beta. The period of the research was between 1947 and 1965 and the statistical population involved 307 companies listed in US Stock Exchange. They used regression for testing the research hypothesis. Results reflected a significant relationship between only three variables namely dividends, asset growth and income standard deviation with systematic risk. The relationship between the first variable and risk was negative and the relationship between the second and third variables was positive. In general the results indicate that the accounting variables listed above can only justify 45 percent of the partial fluctuations of the market beta.

Gonedes (1973), has examined the relationship between accounting numbers and risk. In his study independent variables include net income, accounting income and stockholders' net worth and the dependent variable is systematic risk. Time span of the research involves the years between 1946 and 1967 and the statistical population consists of 99 companies listed in New York Stock Exchange.

He has designed his hypotheses as follows:

- A significant relationship exists between operational income and systematic risk

- A significant relationship exists between net income and systematic risk

- A significant relationship exists between changes in stockholders' net worth and systematic risk

To test the hypotheses, correlative tests and regression analysis was used. Results from analysis of data indicated the approval of all three hypotheses. Therefore, Gonedes concluded that considering the significant relationship between these variables and market risk, information relating to accounting variables is useful in the assessment of systematic risk.

Beaver and Manegold (1975), have also examined the relationship between certain accounting ratios and systematic risk. The objective of the study has been to examine the relationship between systematic risk of the market and risks based on accounting numbers. They have considered the ratio of net income to market value of common stocks, the ratio of asset return, and the ratio of return on net worth, as indices of accounting variables. The statistical population of the research consisted of 254 companies listed in New York Stock Exchange between 1955 and 1961. The research was of a correlative type and regression analysis was used for testing the hypotheses. Results indicated that a significant relationship exists between accounting ratios mentioned above and systematic risk.

Bildersee (1975), has examined the relationship between accounting variables and market risk. The objective of this research is to study the usefulness of accounting information in assessing systematic risk. Therefore, previous researches and variables used in them were studied and accordingly certain accounting variables were chosen as independent variables. These include the ratio of liabilities to common stock, liabilities to total assets, liabilities to market

value, quick ratio, current ratio, dividend ratio, interest coverage ratio, EPS growth, Company Size, Accounting Beta and the ratio of preferred stock to common stock. The statistical population of the research consisted of 71 companies listed in New York Stock Exchang between 1956 and 1966. Correlation coefficients and regression analysis were used. Results of the study reflected that among all variables mentioned above only 5 held significant relationships with systematic risk. These variables included: ratios of liabilities to common stock, preferred to common stock, sales to common stock, current ratio and the variability of income coefficient.

Ismail & Kim (1989), have performed a study titled "Studying the Relationship between Variables Related to Cash Flows and Systematic Risk". They have used variables indicative of cash flows of the entity. Variables selected for this purpose included stockholders' net worth, stockholders' net worth and depreciation, stockholders' net worth plus depreciation and deferred taxes, net cash flows from operations. The information was obtained from financial statements of 272 companies listed in New York Stock Exchange between 1975 and 1987. Considering the research was of a correlative type, correlation coefficients and regression analysis were used. Results indicated that a significant relationship exists between all four variables mentioned above and systematic risk.

Brimble and Hodgson (2003), studied the relationship between accounting variables and risk. They divided accounting variables into three categories

namely, operational , financing and growth risks.statistical population of the research consists of 129 companies listed in Australian Stock Exchange between 1991 and 2000. The financial information relating to them were obtained and studied and results from regression tests indicated that more than 57 percent of changes in systematic risk could be verified according to the variables selected in the model.

Fraser et al. (2004), examined the partial relationship between risk and return. Information relating to returns was obtained from monthly publications of the British Stock Exchange from February 1975 to December 1996. Beta, in this study, represented risk and was calculated using the ARCH model. The research was of a correlative type and regression analysis was used for this purpose. Results of the study indicated that a negative partial relationship existed between risk and return.

Elyasiani and Iqbal Mansur (2005), studied the relationship between risk based market figures and accounting financial ratios. The statistical population consisted of 52 financial institutions in Japan, for which the financial information was obtained and examined between 1986 and 1996. Results from regression tests indicated that a significant relationship existed between financial ratios and market risk. They also performed a comparative study on the relationship between risk and financial ratios that play a critical role in decision making between the United States and Japan. Results of this study showed that the relationship between risk based on market figures and financial risk is weaker in

Japanese financial institutions than American institutions for the same period of time.

Abdelghany (2005), has studied the relationship between market risk and risk based on accounting figures. The objective of this study has been to determine the level of disclosure of information needed by companies for the purpose of predicting market risk; since disclosure of certain accounting variables that have a significant relationship with risk may not be made according to SEC regulations, or be inadequate. For this purpose 323 companies listed in New York Stock Exchange were tested. Research variables included financial and operational leverage, company size, current ratio, income growth and dividends distributed. He used regression analysis. Results of the research reflected that all research variables have a significant relationship with systematic risk (Beta).

Giner and Reverte (2006), have examined the information content of accounting figures for assessing investment risks. The objective of this study was to assist investors in measuring capital expenses and to make the appropriate decisions regarding the allocation of resources. For this purpose, the relationship between capital expense and risk based on accounting figures was tested. The statistical population of the study involved all non-financial companies listed in Madrid Stock Exchange between 1987 and 2002. For the calculation of capital expenditures, a valuation method based on retained earnings was used. Results indicated that a significant relationship existed between capital expenditure and risk based on accounting figures .

Hopkins et al. (2006), studied the relationship between income and risk. For this purpose three variables were used as indices namely net income, comprehensive income and income based on market value. The statistical population of the research included 202 commercial banks of the United States between 1994 and 2004. Results from correlation tests and regression analysis indicated that the correlation coefficient between income based on market value and risk is higher than the other variables. In other words, income based on current market values holds a closer relationship with risk as compared to the other variables.

Campbell et al. (2007), have studied the relationship between upper level managers' incentives and the non-financial risk of companies. The objective of this study has been to investigate the effects of the performance of upper level managers and their incentives on company risk. The statistical population of the study included 514 companies active in petrochemical products and listed in New York Stock Exchange between t 1992 and 1994. The time span was chosen as such since these were the first couple of years that new regulations had been enforced for the reporting of information relating to companies active in the mentioned industry. They used correlation coefficient and regression analysis to test the relationship between these two variables. Results of the study reflected that a significant relationship exists between upper level managers' incentives and non-financial risk.

A number of studies on risk have also been carried out in Iran. Among these include researches by Ahmadpour and Namazi(1998) titled "The Effects of Operational and Financial Leverage and Company Size on Systematic Risk, Nowravesh and Vafadar(1999) titled "Investigating the Usefulness of Accounting Information in Assessing Market Risk" and Namazi and Khajavi(2004) titled "Usefulness of Accounting Variables in Predicting Systematic Risk in Companies Listed inTehran Stock Exchange".

The difference between the present study and similar studies performed in Iran is that none of the previous studies had classified accounting variables based on their influence on risk.

Research Hypotheses

The following hypotheses have been introduced according to the literature:

First Hypothesis: A significant relationship exists between operational and systematic market risk.

Second Hypothesis: A significant relationship exists between financing and systematic market risk.

Third Hypothesis : A significant relationship exists between growth and systematic market risk.

Method of Research

The present study attempts to investigate the usefulness of accounting variables in market risk assessment. The study is an applied and historic type.

If collected data relates to events that have occurred in the past, the research can said to be historic (Delavar, 2001). The objective of applied researches is to expand the applied body of knowledge in a specified field (Sarmad et al., 2002). The present research can also be considered a descriptive type based on the data collection method and a correlative study based on the method of testing the hypotheses.

Following the collection of data, accounting variables that were classified into three groups namely operational, financing and growth risk, were calculated in the excel software and subsequently the normality of data distribution (Kolmogorov-Smirnov) was tested. In case the distribution of variables is not normal, results from the analysis of data may not be reliable. Correlation of independent and dependent variables was tested using the multi variable regression model and the hypotheses were also tested using Excel and SPSS 13.0 software and correlation coefficient analysis.

Research Variables

To determine research variables, twelve accounting variables were chosen based on the literature and were classified into three categories, namely operational, financing and growth risks, as reflected in Table 1.

Table 1: Independent and Dependent Variables			
	Type of Risk	Variable	Abbreviation
Independent	Operational Risk	Accounting Beta Income (Earnings) Variance Earnings Symbol Cash Flows Dividend Paid Ratio Operational Leverage Liquidity	β_{Accit} EV_{it} ES_{it} CF_{it} DPR_{it} $OPLev_{it}$ Liq_{it}
	Financing Risk	Financial Leverage Interest Coverage	$FLev_{it}$ $Icov_{it}$
	Growth Risk	Growth Size Market to Book Value	Gth_{it} $Size_{it}$ $Mrkt/Bk_{it}$
Dependent	Systematic Market Risk	Beta	β_i

The multi variable regression was then used to illustrate the relationship between accounting variables and systematic risk (Brimble & Hodgson, 2002). The model has been presented as follows:

$B_{it} = \alpha_i + b_1\,\beta_{Accit} + b_2\,EV_{it} + b_3\,ES_{it} + b_4\,CF_{it} + b_5\,Gth_{it} + b_6\,Size_{it} + b_7$

$DPR_{it} + b_8\,Liq_{it} + b_9\,Flev_{it} + b_{10}\,Icov_{it} + b_{11}\,OPLev_{it} + b_{12}\,Mrkt/Bk_{it} + \varepsilon_{it}$

B_{it} = Systematic Market Risk

β_{Accit} = Accounting Beta

EV_{it} = Earnings Variance

ES_{it} = Earnings Symbol

CF_{it} = Cash Flows

Gth_{it} = Growth

Size$_{it}$ = Size

DPR$_{it}$ = Dividend Paid Ratio

Liq$_{it}$ = Liquidity

Flev$_{it}$ = Financial Leverage

Icov$_{it}$ = Interest Coverage

OPLev$_{it}$ = Operational Leverage

Mrkt/Bk$_{it}$ = Market to Book Value

$α_i$ Regression Slope and $ε_{it}$ represent calculation errors

Research variables have been calculated as follows:

Operational Risk

This category of risks is made up of seven variables namely, Accounting Beta, Earnings Variance, Earnings Symbol, Cash Flows, Dividend Paid Ratio, Operational Leverage and Liquidity.

1) *Accounting Beta*

Beta represents systematic risk based on accounting figures and is related to extensive economic factors. Accounting Beta is calculated as follows (Bowman, 1979):

$β_{ACCIT}$ = Cov (Xi, Xm) / Var (Xm)

Where β_{ACCIT} is Accounting Beta, X_i is yield for company I, and X_m is yield for market portfolio.

2) *Income (Earnings) Variance*

To calculate standard deviation of earnings in time t, average net income was first calculated for a time period of ten years, and subsequently the standard deviation was calculated relative to the average figure (Beaver, Kettler & Scholes, 1970; Bildersee, 1975; Castagna & Matolcsy, 1975).

3) *Earnings Symbol*

Is an implicit variable which is shown with zero where income is negative in a specific time period, and is represented by one where income is a positive number (Hayn, 1995).

4) *Cash Flows*

Cash flows is defined as the stockholders' share of revenue divided by beginning of the year market value of capital (Ismail & Kim, 1989).

5) *Dividend Paid Ratio*

The ratio was calculated by dividing the average dividends paid in period t to stockholders' investing in common stock (Beaver, Kettler & Scholes, 1970; Castagna & Matolcsy, 1978). In other words the ratio was calculated through dividing dividends paid for each share by earnings per share.

6) *Operational Leverage*

To calculate the operational leverage, income before interest expense and taxes in a specific period is divided by sales in the same period (Lev, 1974; Rosenberg & Mc. Kibben, 1973). The ratio can also be considered as premium risk of income (Penman, 2001).

7) *Liquidity*

To calculate liquidity in this study, the ratio of current assets to current liabilities at year end was used. The ratio is equal to operational liability leverage risk (Castagna & Matolcsy, 1978; Beaver, Kettler & Scholes, 1970).

Financing Risk

This risk involves two accounting variables namely financial leverage and interest coverage, which are significant in the determination of the company's financing status.

Financial Leverage

To calculate the financial leverage in this research, total liabilities in a specific period have been divided by total assets in the same period (Beaver, Kettler & Scholes, 1970; Castagna & Matolcsy, 1978).

Interest Coverage

This variable has been calculated as income before taxes plus total interest expense divided by total interest expense in period t (Rosenberg & Marathe, 1975; Bildersee, 1975).

Growth Risk

This risk is made up of three groups of accounting variables namely growth, size and the market to book value ratio.

1) Growth

For purposes of calculating growth, the logarithm of changes in total assets throughout the period has been used, such that total assets at the beginning of the year have been deducted from year-end total assets and then the related logarithm calculated (Beaver, Kettler & Scholes, 1970; Castagna, Matolcsy, 1978).

2) Size

To calculate the variable of size, criteria such as the logarithm of total assets or sales has been used. However due to inflation and the irrelevance of historic figures relating to assets, the logarithm of the market value of stockholders' equity at year-end was used to measure company size (Ataise, 1985; Freeman, 1987).

3) Market to Book Value Ratio

In the present study, market to book value ratio per share, is equal to the market value of common stocks at year-end divided by the book value of the same stocks at the same date.

Period of Research and Statistical Population

The time period of the research is between 1997 and 2006. Since no information was available for the year 2006 for all the industries listed in TSE, three industries namely automobiles and parts, chemical products and machinery and equipment were chosen on the basis of the criteria mentioned in the research. Among the 97 companies listed in the mentioned three industries at the end of the year 1996, 61 companies were qualified and information relating to a period of ten years (1997-2006) was studied. Table 2, reflects the number of companies in each of the three industries and the number of companies selected as the statistical sample.

Table 2: The number of sample companies

Category	Industry	No. of Companies Active in Industry	No. of Companies in Sample
1	Automobiles and parts	30	19
2	Chemical Products	34	19
3	Machinery and Equipment	33	22
	Total	97	60

Research Results

To test the normality of data distribution, the Kolmogorov-Smirnov test was applied and the following hypotheses introduced:

H_0: Data distribution is normal

H_1: Data distribution is not normal

According to the information in Table 3, the significance of all variables was higher than the standard level (α= 5%), therefore H_0 was approved.

Table 3: Normality of Data Distribution using the Kolmogorov-Smirnov Test

Variables	Kolmogorov-Smirnov Parameter	Significance
Accounting Beta (β_{ACCIT})	0.960	0.313
Earnings Variance (EV_{it})	0.694	0.734
Earnings Symbol (ES_{it})	0.493	0.212
Cash Flow (CF_{it})	0.959	0.323
Dividend Paid Ratio (DPR_{it})	0.477	0.645
Operational Leverage ($OPLev_{it}$)	0.898	0.454
Liquidity (Liq_{it})	0.676	0.678
Financial Leverage ($Flev_{it}$)	0.565	0.220
Interest Coverage ($Icov_{it}$)	0.343	0.567
Growth (Gth_{it})	0.567	0.564
Size ($Size_{it}$)	0.981	0.259
Market to Book Value Ratio ($Mrkt/Bk_{it}$)	0.212	0.312

Since the hypotheses attempted to find a relationship between the two variables, primarily the correlation coefficient (r) of the two variables was calculated. Subsequently, the significance of the correlation coefficient was tested.

Table 4: Table of Regression Coefficients

αi (Constant)	-19.691
Earnings Variance (EV_{it})	-1.000000054
Earnings Symbol (ES_{it})	0.756
Cash Flow (CF_{it})	-0.445
Growth (Gth_{it})	-1.394
Size ($Size_{it}$)	2.107
Dividend Paid Ratio (DPR_{it})	0.194
Liquidity (Liq_{it})	0.051
Financial Leverage ($Flev_{it}$)	3.733
Interest Coverage ($Icov_{it}$)	-3.0000067
Operational Leverage ($OPLev_{it}$)	1.070
Market to Book Value Ratio ($Mrkt/Bk_{it}$)	-0.006

Therefore, the regression model was presented as follows:

B_{it} = -19.691 -1.000000054 EV_{it} + 0.445ES_{it} - 0.756 CF_{it} -1.394 Gth_{it}

+2.107$Size_{it}$ + 0.194DPR_{it} + 0.051 Liq_{it} + 3.733$Flev_{it}$ -3.0000067 $Icov_{it}$

+1.070 $OPLev_{it}$ -0.006$Mrkt/Bk_{it}$

Considering the above mentioned facts, results of each test performed for

the hypotheses can be presented as follows:

Results Obtained from Testing the First Hypothesis

First Hypothesis:

A significant relationship exists between operational and market systematic risk.

The corresponding statistical hypothesis may be defined as follows:

H_0: No significant relationship exists between operational and systematic market risk

H_1: A significant relationship exists between operational and systematic market risk

Table 5 reflects the results obtained from testing the first hypothesis.

Table 5: Results of Testing the First Hypothesis

Variables	Market Beta	Earnings Variance	Earnings Symbol	Cash Flows	Dividends Paid Ratio	Financial leverage	Liquidity
Pierson's Correlation	1	0.011	0.009	0.012	0.006	0.01	-0.032
Probability	----	0.935	0.817	0.759	0.890	0.810	0.425
Number	610	61	610	610	610	610	610

When testing the first hypothesis, it was concluded that despite P-value $\geq \alpha =$ 5%, none of the variables are significant. Therefore, it can be said that no significant relationship exists between operational and systematic market risk. The results did not conform to the conclusions obtained in the year 2002. Brimble and Hodgson (2002), have concluded that the accounting variables that compose operational risk in assessing market risks are material and contain useful information.

Results Obtained from Testing the Second Hypothesis

Second Hypothesis:

A significant relationship exists between financing and systematic market risk.

The corresponding statistical hypothesis may be defined as follows:

H_0: No significant relationship exists between financing and systematic market risk

H_1: A significant relationship exists between financing and systematic market risk

Table 6 reflects the results obtained from testing the second hypothesis.

Table 6: Results of Testing the Second Hypothesis

Variables	Market Beta	Financial Leverage	Interest Coverage
Pierson's correlation	1	0.29	0.000
Probability	----	0.470	0.999
Number	610	610	610

When testing the second hypothesis, it was concluded that despite P-value ≥ α = 5%, none of the variables are significant. Therefore, it can be said that no significant relationship exists between financing and systematic market risk. The results conformed to the conclusions obtained in the year 2002. Brimble and Hodgson (2002), have concluded that the accounting variables that compose financing risks are less material in predicting future risk.

Results Obtained from Testing the Third Hypothesis

Third Hypothesis:

A significant relationship exists between growth and systematic market risk.

The corresponding statistical hypothesis may be defined as follows:

H_0: No significant relationship exists between growth and systematic market risk

H_1: A significant relationship exists between growth and systematic market risk

Table 7 reflects the results obtained from testing the second hypothesis.

Table 7: Results of Testing the Third Hypothesis

Variables	Market Beta	Financial Leverage	Interest Coverage	Book to Market Value
Pierson's correlation	1	0.079	0.036	0.023
Probability	----	0.057	0.376	0.572
Number	610	610	610	610

When testing the third hypothesis, it was concluded that despite P-value $\geq \alpha =$ 5%, none of the variables are significant. Therefore, it can be said that no significant relationship exists between growth and systematic market risk. The results did not conform to the conclusions obtained in the year 2002. Brimble and Hodgson (2002), have concluded that the growth risks contain material information in assessing risks.

Discussion and Conclusion

In the present study, three hypotheses were introduced and tested. Results reflected that no significant relationship exists between any of the variables and systematic market risk.

The absence of any relationship between operational, financing and growth risks with the systematic market risk may be due to the fact that the three risks mentioned above include variables based on historical accounting values and not current market values.

Since the model introduced in this study had never been tested before in Iran and the accounting variables never classified according to their effects on risk, no comparison could be made between results obtained from testing the hypotheses and results from any studies performed within the country.

Results indicate that mere reliance on accounting information presented by companies cannot be a basis for assessing the market beta and it is quite necessary to recognize other factors influencing risks within a company especially in decision making issues. On the other hand it cannot be claimed solely on basis of results obtained herein that accounting information are not useful in the assessment of systematic market risk. Such a claim would be made only upon complimentary researches with due considerations to fluctuations in the country's economy and subsequently in the stock market.

Comparison of the Value Relevance between the Purchase and Rental Treatment of Leases

Abstract

The purpose of this paper is to compare the earnings value relevance between rental and purchase treatments, i.e. to examine whether the capitalization of operating leases is appropriate in terms of income measurement rather than as recognition on balance sheets. Because the information on the "as-if" purchase treatment of operating leases is not disclosed, the difference in the value relevance between the rental and purchase treatment of finance leases is examined in order to obtain implications for operating leases. The results show that the value relevance of earnings-via purchase treatment rather than by rental treatment is significantly higher only in 2003. This might imply that investors utilize footnote information only in particular situations.

Although we need further examination of why investors evaluate leases differently only in 2003 and it is important to expand this implication carefully in order to evaluate the relevance of capitalization of operating leases, this paper offers serious implications for the FASB/IASB project.

1   Introduction

The recent joint project of the International Accounting Standard Board (IASB) and the

Financial Accounting Standard Board (FASB) has been to discuss the capitalization of

operating leases as purchase rather than rental transactions.   Prior research such as

that of Ely (1995) and Lindsey (2006) show that the "as-if" capitalized value of

operating leases disclosed in footnotes is related to stock price and equity risk. If

accepted, however, this new proposal will change the treatment of operating leases not

only with respect to balance sheets, but also with respect to income statements. This

paper focuses on the difference in the value relevance of earnings between the two

systems.

Since under current U.S. GAAP the earnings effect of "as-if" capitalized operating

leases is not available, we cannot compare the value relevance of earnings between in

the two systems. Under Japanese GAAP, however, we are able to get information

through 2008 on the earnings of finance leases (known as capital leases in the U.S.)

both by purchase treatment and rental treatment. Finance leases were typically treated

as rentals on the body of financial statements. Supplementary information with respect

to earnings when lessees capitalize finance leases (including the amounts of lease

assets and liabilities, the depreciation expense of lease assets, and the interest

expense for lease liabilities) were disclosed only in the footnotes. I have chosen to

examine a Japanese sample because earnings information in Japan is available both

when finance leases are treated as rentals and (when earnings are adjusted using information found in the footnotes) when finance leases are treated as purchases.

This paper is organized as follows: Section 2 describes the discussion of accounting for leases in the U.S., G4+1 and Japan, Section 3 provides a review of prior research, Section 4 develops hypotheses and describes the research design, and Section 5 summarizes the sample and empirical results. Section 6 discusses the implications of the empirical results and discusses future issues.

2   Accounting for Leases

2.1   Discussions in the U.S. and the IASC

Accounting standard setters in the U.S. such as AICPA, APB and FASB have been expanding the range of the types of leases that they believe should be capitalized by lessees. Although leases are legally regarded as executory contracts and accountants have generally agreed that the rights and obligations arising from executory contracts should not be recognized on balance sheets, standard setters believe that non-cancellable lease commitments are in fact liabilities to lessees and therefore consider it insufficient to disclose this information only in footnotes[85]. .

Under current U.S. GAAP, only capital leases (also known as "finance leases" in Japan) are capitalized. This is because capital leases are non-cancellable and the lessees take almost all of the benefits and risks associated with the leased property.

---

[85] FASB (1984), para.9

Such a lease is believed to bear a greater similarity to a purchase contract than it does to a rental contract. As with purchase contracts, the finance lease is considered fulfilled at the time of delivery of the asset to the lessee. (If it is a purchase contract, the contract is considered fulfilled at the time of delivery of the property.) As such, the lessee should recognize the asset and liability associated with the executed contract because finance leases are accounted for as the acquisition of an asset and the incurrence of an obligation by the lessee in the same way as an installment purchase is. All other kinds of leases are classified as operating leases and their rental is charged to expense over the lease term as it becomes payable. Operating leases are considered to be executory contracts in the same way as rental contracts are regarded as executory contracts. In both cases, assets and liabilities are not recognized on the lessees's balance sheet.

In 1996 and 2000[86], G4+1[87] published special reports which proposed that operating leases be capitalized. In their framework, a non-cancellable operating lease is regarded as an installment purchase that allows the purchaser the right to use, but not dispose of the property. Since they believe that the rights and obligations arising from an operating lease meet the definition of an asset and liability, they argue that a

---

[86] Mcgregor (1996), Nailer *et al.*(2000)

[87] G4+1 was a working group consisting of members of the standard-setting bodies of Australia, Canada, New Zealand, the UK, the USA and International Accounting Standards Committee (IASC; the predecessor of IASB).

non-cancellable lease should be capitalized on the lessee's balance sheet[88] and that

the resulting asset and liability should be recognized as the present value of the

minimum lease rentals at the inception of the lease. The lease asset is subsequently to

be amortized over the lease term and the lease liability is to be reduced by the part of

the principal of the lease payment calculated based on the discount rate, which

determines the present value of the minimum lease rentals.

2.2 Accounting for leases in Japan

ASBJ, the Accounting Standard Board of Japan, released the new accounting

standard for leases in 2006. This new accounting standard which became effective in

March 2009 is very similar to the SFAS No.13 and IAS No.17 standards.

The older accounting standard was released by the Business Accounting Council

of the Japanese Ministry of Finance[89] (the present Financial Service Agency) in 1993.

Under this standard, lease commitments were divided into two categories: finance

leases and operating leases. The Business Accounting Council's definition of a finance

lease is almost identical to the SFAS's definition of a capital lease[90]. Under the older

---

[88] Nailer *et al.* (2000), p.22, par.38.

[89] Prior to 2001, the public sector set accounting standards. The private sector, the Accounting

Standard Board of Japan (ASBJ) was established in 2001 and has been the standard setter

ever since. The ASBJ published new accounting standards for leases which abolished the

exception for capital leases. The new standards became mandatory in 2007.

[90] Income measurement for lessors is calculated slightly differently in Japan than it is in the U.S.

standard, a finance lease was accounted for as a purchase-with-loan. Note, however, that this standard allowed lessees to avoid capitalizing the type of finance lease that did not transfer ownership of the property to the lessee by the end of the lease term. Because firms preferred this off-balance treatment, most finance-lease users arranged lease contracts so as not to be obliged to capitalize them.

Lessees that do not capitalize finance leases are instead required to disclose capitalized information (such as the present value of lease liabilities, the acquisition cost of lease assets, the book value of lease assets after depreciation, the amount of their lease rentals, and depreciation expenses on lease assets and interest expenses on lease liabilities) in the footnotes of their financial statements. Users whose lease liabilities are less than 10% of the sum of the book value of their PP&E and their lease liabilities[91] are also allowed to use a concise footnoting method for disclosing their capital leases. This method allows users to substitute the gross amount of their lease rentals for the present value of the measurement of lease assets and liabilities. In this case, the book value of lease assets and liabilities is the gross amount of the lease

---

In the U.S., the revenue measurement for sales-type leases is to be separated from that of direct financing leases whereas in Japan, we treat both types of leases as finance leases. However because this paper focuses on the earnings of lessees, this makes no difference to my argument.

[91] $\dfrac{Lease\,Liability}{BV\,of\,PPE + Lease\,Liability} \geq 10\%$

rentals added to the interest expense on lease liabilities. (Note as well that this information will not appear in the footnotes because the book value of liabilities is the gross amount of lease rentals and the interest rate considered in the measurement is set at zero.) We call the gross amount method the "interest-inclusive method" and the discounted method (i.e. the measurement method that excludes interest) the "interest-exclusive method."

In order to calculate purchase-treatment earnings, we need the information available in the footnotes via the "interest-exclusive method." Here, the adjusted earnings are calculated by adding rental payments back to the reported earnings on income statements and subtracting the depreciation expense of leased assets and the interest expense of lease liabilities.

3   Previous Research

There is a great deal of capital-market research focused on lease accounting. Most fall into one of two categories: the first category investigates the effect of the adoption of ASR No.147 (1973) and SFAS No.13 (1976) on capital markets. ASR No.147, an SEC regulation in effect until 1976, ruled that because most leases were not capitalized, finance leases (known as capital leases under SFAS No. 13) were to be disclosed. As such, "as-if" capitalized financing lease information (the present value of lease rentals, interest rate implicit in computing the present value, and the impact on net income) was available under ASR No.147, and "as-if" capitalized operating lease information (the future minimum lease payments and rental expenses for each period for which an

791

income statement was presented[92]) was available under SFAS No.13. Murray (1981) investigated the market reaction associated with moving lease disclosures from footnotes to the body of financial statements and found that there was no reaction to this change in accounting rules. This finding implies that disclosure in footnotes is of equal value to recognition on balance sheets.

The second area of research investigates the value relevance of footnote information, i.e. financing lease information under ASR No.147 and operating lease information under SFAS No.13. Ro (1978) and Bowman (1980) show that markets evaluate the footnote information of "as-if" capitalized financing lease under ASR No.147. Ely (1995) and Lindsey (2006) examine the value relevance of footnote information of "as-if" capitalized operating leases under SFAS No.13 and show that in general, footnote information on leases is evaluated in determining stock price. Note that all of the above research focuses only on the balance sheet effect of capitalization.

There is very little research on the earnings effect of capitalization. Under current U.S. GAAP, the earnings effect of "as-if" capitalized operating leases is not available. ASR No.147 (1973) required the disclosure of lease information having to do with non-capitalized financing leases, such as the impact on net income if such leases had been capitalized. Ro (1978) investigated the market reaction associated with this additional disclosure and showed that the difference between purchase and rental treatment was related to the distribution of returns on securities. Perhaps surprisingly,

---

[92] FASB (1976), para.16

there is no research that compares the value relevance of earnings by purchase treatment with that of earnings by rental treatment. This paper therefore examines the difference in the value relevance of earnings when finance leases are treated as purchases and when they are treated as rentals.

4 Developing Hypothesis and Research Design

As described above, the purpose of this paper is to compare the earnings value relevance between rental and purchase treatments by using a sample drawn from Japan in which rental-treatment earnings are reported in the body of income statements and purchase-treatment earnings, which require calculation adjustments derived data available in the footnotes.

There is empirical evidence that investors efficiently incorporate information derived both from footnotes and from the body of income statements (Murray (1981), implying that the former is not inferior to the latter. If adjustment earnings explain stock prices more fully than do earnings disclosed in the body of income statements, we can reasonably infer that adjustment earnings offer more information than either of the other disclosure methods. Information offered as a result of the earnings-by-purchase-treatment method offer data (such as the lessee's incremental borrowing rate) not included in the earnings by rental treatment method. We can therefore expect that the earnings of firms that disclose lease expenses via the purchase treatment have incremental explanatory power with respect to stock prices. The hypothesis is therefore as follows:

H_1: The earnings of firms that disclose lease expenses via the purchase-treatment

methodology have incremental explanatory power with respect to stock prices.

Since this paper investigates the value relevance of earnings to stock prices, its

model is based on the permanent-earnings-discount-model.

The relation between the market value of a firm's common equity and earnings is

given by:

$$MVE_{it} = \frac{E(\pi_{pit})}{r_{it}} \qquad (1)$$

Where MVE_{it} is the market value of equity for firm i at year t, $E(\pi_{pit})$ are expected

permanent earnings for firm i at time t, and r_{it} is the discount rate for firm i at time t. The

net income includes operating profit, ordinary profit and contains transitory components

(similar to extraordinary items in U.S. GAAP) including "special profits and loss" in

Japanese GAAP. As such, I use the ordinary profit (OP) (the sum of operating income

and financing income) as the proxy variable for permanent earnings.

$$P_{it} = \alpha + \beta_0 OP_{it} + \beta_1 D_{OP} * OP_{it} + \beta_2 \sum INDUSTRY + \varepsilon_{it} \qquad (2)$$

I input the stock price of firm i at the fiscal year end of year t (P_t) for the market value of

equity. (Note that positive and negative earnings typically have different coefficients). I

then consider the dummy variable for negative operating profit (D_{OP}). When OP has a

negative value, D_{OP} is assigned a value of one, otherwise it is set at zero.

$INDUSTRY_{it}$ is a categorical variable to control for the effect of industries in

accordance with the industrial code provided by Nikkei NEEDS.

For the regression analysis for H_1, regression (2) is modified as below:

$$P_{it} = \alpha + \beta_0 OP_{it} + \beta_1 D_{OP} * OP_{it} + \beta_2 D_{PTit} * OP_t + \beta_3 \sum INDUSTRY_{it} + \varepsilon_{it} \quad (3)$$

D_{PT} denotes the dummy variable for purchase treatments that are described in footnotes. When the footnote information is disclosed through the interest-exclusive method, D_{PT} takes one, otherwise it takes zero. As we can expect that the earnings of firms that disclose lease expenses via the purchase treatment have incremental explanatory power with respect to stock prices, $\square_2$ is expected to be different to zero. To avoid the heteroscedasticity problem, all variables are deflated by the prior stock price (P_{t-1}).

Under Japanese GAAP, the "interest-exclusive method" is only used by firms whose lease liabilities are more than 10% of the sum of the book value of their PP&E and their lease liabilities[93].

I then compare the value relevance of earnings by rental treatment with that of adjusted earnings by purchase treatment. Therefore:

H_2: The adjustment-ordinary profits garnered by using footnote information are more relevant to stock prices than are ordinary profits reflected on income statements.

If investors adjust ordinary profit by using information provided in the footnotes, the regression formula can be modified as follows:

$$P_{it} = \alpha + \beta_0 adjOP_{it} + \beta_1 D_{adjOPit} * adjOP_{it} + \beta_2 \sum INDUSTRY_{it} + \varepsilon_{it} \quad (4)$$

---

[93] Note that I cannot deny the possibility that D_{PT} of regression (5) could be a proxy for something related to incentives for leases.

Where *adjOP* is calculated by adding lease rental paymentsback into the ordinary profit

reported on the income statement and by reducing the depreciation expense on lease

assets and interest expense on lease liabilities. (*adjOP=OP + lease rentals -*

deprecation expenses on lease assets + interest expenses on lease liabilities.) To

assess the relative explanatory power of ordinary profits and adjusted ordinary profits, I

adopt the Vuong test that tests the superiority and inferiority between the models[94]. I

then compare the explanatory power of $adjOP_t$ with *OP* by using the Vuong test for H_2.

5 Empirical Results

The sample consists of firm-year observations from 2000 to 2006 pertaining to all

Japanese stock markets. I obtained data based on the following criteria: data were to

(1) be from non-financial firms only, (2) have a fiscal year ending March 31[95], and (3)

have no missing values for any of the variables. Accounting figures and stock prices on

March 31 were obtained from Nikkei NEEDS. *OP* was extracted from income

statements and "as-if" capitalized lease expenses were extracted from footnotes. All

variables were calculated per share and deflated by prior stock value P_{t-1}.

I created a dummy variable for firms that disclose finance lease expenses in

footnotes via the interest-exclusive treatment (D_{PT}). When a firm discloses the interest

---

[94] See Ota and Matsuo (2004).

[95] In Japan, the typical end of the fiscal year is March 31. When the stock market was closed on

March 31, I took the stock prices from the last day of March during which the market was open.

on financing lease rentals, (i.e. the firm has disclosed both depreciation expense and interest expense) it has treated the lease as if it were a purchase,

D_{PT} takes one, and zero otherwise. I also created a dummy variable for finance lease users (D_{FL}) that takes one when a firm discloses financing lease rentals and takes zero otherwise.

Panel A of Table 1 summarizes the descriptive statistics of each variable. The mean of D_{FL} shows the proportion of the finance-lease users in the sample. The table shows that approximately 95% of the sampled firms use finance leases. This might be evidence that finance leases are very common in Japanese firms because lessees can take off-balance sheet treatment and because firms prefer finance leases to purchases-with-loan. From the perspective of tax savings, the amount of a finance lease disbursed can be allocated over a shorter period than in the case of a "purchase-with-loan," under the condition that the sum of the finance lease rentals are equal to that of "purchase-with- loan," or installment purchases. The mean of the D_{PT} is approximately 35%. Firms disclosing the interest paid in financing lease rentals are disclosing information via the "interest-inclusive method." In this case, D_{PT} takes one, and zero otherwise. The mean of D_{PT} therefore shows the proportion of firms in the sample that use the interest-inclusive method. The results imply that not all finance lease users disclose information via the interest-inclusive method.

Note as well that the difference between *OP* and *adjOP* is very subtle. The fact that the ratio of disclosure of information with respect to purchase treatment is only 35%

means that there is no difference in 65% of the sample. The substantial difference of

OP and adjOP can be seen in Panel B of Table1.

Table 2[96] shows the results of regression (2) by using the sample for 2000 to 2006.

The coefficient on $D_{PT}*OP_t$ ($\beth_2$) is significantly different to zero at the 5% level in 2002

and at the 1% level in 2003. This result shows that D_{PT} is not always related to stock

price, because the coefficient on $D_{PT}*OP_t$ is not consistently significant over the sample

period.

Table 3 shows the results of the Vuong-test for regressions (3) and (4) using

samples from 2000 to 2006. This table shows that adjusted ordinary profits do more to

explain stock prices than do ordinary profits on income statements in 2003 at the 10%

level. Note that in other years there is no significant difference between the explanatory

power of ordinary profits and that of adjusted ordinary profits.

In 2003, H1 is supported at the 1% level and H2 is supported at the 10% level.

These results imply that investors utilize the information only in very specific situations.

One reason considered is the change in accounting standards for lease amendments.

The ASBJ organized the committee that deliberated over lease accounting in July of

2002. The aim of the committee was to make finance lease users capitalize finance

leases. As such, investors may have regarded finance leases as purchases in March of

2003. This scenario, however, leaves us with the following problem: Why is it that in

---

[96] The table omits results of my controlling for the effect of industries in which I use the dummy

variables.

2004 and afterwards, adjusted ordinary profits do not do more to explain stock prices

than do ordinary profits?

Table 4 shows another reason considered. This table shows interest rates for

finance leases and newly issued government bond yield from 2000 to 2006. The

interest rates of finance lease are roughly calculated as the average of the finance

lease interest rates (interest expense/lease liabilities) of the firms that disclose footnote

information via the purchase treatment. The table shows that the interest rate in 2003

was generally lower than in other years and that the interest rate on finance leases in

2003 was not as low as in other years studied. Since finance lease contracts are non

cancellable, lessees can not refinance lease debts even though the interest rate is very

low. This might imply that investors make a certain evaluation with respect to lessees'

inability to refinance and did so particularly in 2003.Future studies examining the

relationship between economic circumstances (particularly interest rates) and

economic function of leases will clarify the validity of these proposed arguments.

6   Conclusions

The purpose of this paper is to compare the earnings value relevance between

rental and purchase treatments, i.e. to examine whether the capitalization of operating

leases is appropriate in terms of income measurement rather than as recognition on

balance sheets. Because the information on the "as-if" purchase treatment of

operating leases is not disclosed, the difference in the value relevance between the

rental and purchase treatment of finance leases is examined in order to obtain

implications for operating leases. The results show that the value relevance of earnings-via purchase treatment rather than by rental treatment is significantly higher only in 2003. This might imply that investors utilize footnote information only in particular situations, as described above. The two scenarios discussed above have different implications with respect to the FASB/IASB project. If we assume that investors only used footnote information in 2003 because of the accounting amendment, we can assume that the 2003 experience left investors believing that using footnote information was not useful. This would imply that earnings as described via the purchase treatment are not as useful as standard-setting bodies imagine they will be.

On the other hand, if we assume that investors made a certain evaluation with respect to finance lease users because of the lower interest rate, the purchase treatment of finance leases can be imagined to offer more information relevance to the stock value than the rental treatment does.

Although it is important to expand this implication carefully in order to evaluate the relevance of capitalization of operating leases, this paper offers serious implications for the FASB/IASB project.

M&A GOODWILL ACCOUNTING: "THOSE ARE MY PRINCIPLES, AND IF YOU DO NOT LIKE THEM..."

Humberto R Ribeiro[97]

Abstract – The accounting for business combinations has been a fertile source of controversies, to which the accounting for goodwill generated from Merger & Acquisitions (M&A) has made major contributions. Practitioners continue to suffer amidst industry lobbying versus regulators quarrels, and therefore one can argue that in M&A goodwill accounting: "Those are my principles, and if you do not like them ... … well, I have others", as Groucho Marx would say.

The replacement of amortisation of purchased goodwill and other intangible assets with definite life by impairment tests continues to raise concerns and therefore remains an accounting issue. Several authors, such as Hayn & Hughes (2006), questioned the superiority of impairment tests over amortisations, while Massoud & Raiborn (2003) suggested that managerial discretion in applying the goodwill impairment tests reduces the quality of reported earnings. Massoud & Raiborn (2003) also argued that SFAS No. 142 creates opportunities for earnings management, particularly in weak economic periods, where companies can undertake a "big bath", i.e., to recognise big impairment losses in a period when earnings are already negatively affected.

The early 2000's was characterised by an economic downturn, which has resulted in a recession in the USA in the period between March and November 2001, as defined by the National Bureau of Economic Research (NBER). The dot.com bubble collapse, the September 11 attacks, and the numerous accounting and corporate scandals that resulted in the Sarbanes-Oxley act, are some of the events that could arguably trigger

---

[97] The author is Associate Professor of Financial Accounting, Bragança Polytechnic Institute, Portugal, and is developing research at Leicester Business School, De Lontfort University, UK .Correspondence address: Escola Superior de Tecnologia e de Gestão, Apartado 1134, Campus de Sta. Apolónia, 5301-857 Bragança, Portugal, E-mail: hn2rpt@gmail.com.

the recognition of massive losses following impairment testing in fiscal years 2001 and 2002. Significant impairment losses under SFAS 142 could only occur from fiscal year 2002 onwards, as this standard was first adopted in fiscal year 2002 by most companies. Unsurprisingly, a big bath earnings management has occurred in 2002, as documented in the accounting and financial literature. There is however another fact that may have eased the happening of this "big bath": the change in the accounting regulation itself, which has diluted the negative impact on corporate earnings due to impairment charges. A big bath earnings management has occurred in 2002, as documented in the accounting and financial literature (see e.g. Jordan & Clark, 2004, 2005). There is however another fact that may have eased the happening of this "big bath": the change in the accounting regulation itself, which has diluted the negative impact on corporate earnings due to impairment charges. By the means of financial reporting disclosures analysis, this paper examines several aspects of SFAS 142 adoption, namely its significant impact on corporate earnings reported in the USA.

1. Introduction

Before FASB's changes in accounting for business combinations in 2001, the managerial accounting choice preference was clear in the mergers & acquisitions field (M&A): pooling of interests method, regardless its use being conditional to its qualification for a uniting of interests (see e.g. Aboody et al., 2000; Anderson & Louderback III, 1975; Ayers et al., 2000, 2002; Copeland & Wojdak, 1969; Gagnon, 1967; Lys & Vincent, 1995; Nathan, 1988). Management wants to maximize results, and purchase was not a suitable method, as it required goodwill recognition and amortisation, with negative consequences on earnings. Indeed, early studies found that managerial discretion was used in business combinations accounting in order meet

financial reporting objectives, namely to maximize reported earnings (Copeland & Wojdak, 1969).

As referred before, this appetence for pooling of interests was excessive. In fact, diverse anecdotal and empirical evidence suggested that companies could reshape M&A deals, incurring in extraordinary expenses, and even paying higher acquisition premiums, simply to meet AICPA's APB Opinion 16 pooling of interests criteria (see e.g. Aboody et al., 2000; Ayers et al., 2002; Davis, 1990; Hopkins et al., 2000; Linsmeier et al., 1998; Lys & Vincent, 1995; Robinson & Shane, 1990; Walter, 1999; Weber, 2004).[98]

Despite the apparent advantages of pooling over purchase method, several studies detected that pooling method resulted in mechanical effects on companies' financial statements and on the analysis of the financial statements (Jennings et al., 1996; Vincent, 1997), while others documented that the short-window announcement returns were lower for companies pooling than for companies using purchase method (Davis, 1990; Hong et al., 1978; Martinez-Jerez, 2001).

According to Fields et al. (2001), whether shareholders benefit from managerial discretion and whether the benefits outweighed the costs is not clear. However, according to Louis (2004), literature suggested that pooling deals are "bad investment decisions" because managers miss the focus on cash-flows, as they are more concerned with reporting increasing earnings, and also because they constraint the management's ability to sell acquired assets after the acquisition (Lys & Vincent, 1995; Robinson & Shane, 1990). Unsurprisingly, Martinez-Jerez (2003) found that stronger negative market reaction to pooling M&A deals is linked to acquirers that have poor corporate governance.

---

[98] Conversely, Nathan (1988) did not find higher acquisition premiums for companies applying the pooling of interests method.

On the one hand, pooling seemed to underperform purchase method, but on the other, its defenders raised their arguments loud when the FASB proposed to eliminate pooling. Apparently, as theorized by Watts & Zimmerman (1990, 1978). Among pooling supporters were certainly managers more concerned with their contracts, than with the effective economic consequences of the forthcoming changes in M&A accounting. Watts & Zimmerman (1978) suggested that accounting choice may affect shareholders' wealth in case managers' compensation contracts are coupled to financial reporting performance. Indeed, while examining specific characteristics determining which business combinations accounting method is selected by the management, it was found that the percentage of insiders' ownership, and accounting-based compensation plans play an significant role (Dunne, 1990).

2. Literature *ex post* changes in M&A accounting

Following the effectiveness of the new business combinations accounting rules, the debate shifted from pooling elimination to the accounting treatment of purchased goodwill and other intangible assets. Amortisation versus impairment tests became the main issue. SFAS 142 replaced amortisation of acquired goodwill and other intangible assets with indefinite useful lives by impairment tests, keeping amortisation, under certain conditions, only for goodwill and intangible assets with finite useful lives. By doing so, the FASB added volatility to financial reporting. This fact was assumed in SFAS 142. When comparing the differences between SFAS 142 and APB Opinion 17, it is stated that (Financial Accounting Standards Board, 2001b: 5):

> "Because goodwill and some intangible assets will no longer be amortized, the reported amounts of goodwill and intangible assets (as well as total assets) will not decrease at the same time and in the same manner as under previous standards. There may be more volatility in reported income than under previous standards because impairment losses are likely to occur irregularly and in varying amounts."

Certainly there will be more volatility, one could add. Regardless the merits of impairment treatment, which screens continuously for the value of purchased goodwill and other intangible assets, whether such volatility increases the quality of financial reporting, and the usefulness of its users, is not a clear matter. Perhaps the best judgement will come with time, but in the meantime some literature started to examine this issue, providing some early findings. In terms of examples of literature about impairments under SFAS 142, Hayn & Hughes (2006) questioned the superiority of impairment tests over amortisations, while Massoud & Raiborn (2003) suggested that the managerial discretion in applying the goodwill impairment tests reduces the quality of reported earnings. Massoud & Raiborn (2003) argue that SFAS No. 142 creates opportunities for earnings management, particularly in weak economic periods, where companies can undertake a "big bath", i.e., to recognize big impairment losses in a period when earnings are already negatively affected.

The early 2000's was characterised by an economic downturn, which has been declared as a recession in the USA by the National Bureau of Economic Research (NBER) in the period between March and November 2001. The dot.com bubble collapse, the September 11 attacks, and the numerous accounting and corporate scandals that resulted in the Sarbanes-Oxley act, are some of the events that could arguably trigger the recognition of massive losses following impairment testing in fiscal years 2001 and 2002. Significant impairment losses under SFAS 142 could only occur from fiscal year 2002 onwards, as this standard was adopted mostly for fiscal year 2002. Unsurprisingly,

a big bath earnings management has occurred in 2002, as documented in the accounting and financial literature (see e.g. Jordan & Clark, 2004, 2005).

There is however another fact that may have eased the happening of this "big bath": the change in the accounting regulation itself, which has diluted the negative impact on corporate earnings due to impairment charges. This matter is to be studied in the following section.

Some literature cast doubts about the superiority of impairment tests over amortisations (vid. Hayn & Hughes, 2006), and other literature suggested that the managerial discretion in applying the goodwill impairment tests reduces the quality of reported earnings (e.g. Massoud and Raiborn, 2003).

3. Analysis of annual reports

This paper examines the effects of the effectiveness of the new business combinations accounting standards in financial reporting. Accordingly, this section examines whether the new business combinations accounting rules had any significant influence on the financial reporting of companies involved in M&A deals. This is arguably a relevant issue because changes in business combinations accounting have a previous record of controversy as they often lead to significant changes in financial reporting.

3.1. Methodology of analysis

The methodology used in this paper is based on the examination of financial reports from large US corporations. Through the information available on their annual reports, particularly in statements on accounting changes, and in the financial statements notes, the effects on financial reporting due to the new business combinations accounting rules are examined. The financial reporting analysis also allowed estimating the impact of the new accounting standards on corporate results.

The analysis of the effects on financial reporting is not intended to formally test any hypothesis. The analysis has a simple proposition which is to verify whether the changes in business combinations accounting resulted in significant impacts on the financial reporting. This statement could be regarded as a testable hypothesis. However, it is not the purpose of this paper, as this proposition will only be evaluated by the means of qualitative and quantitative analysis of financial reporting data. A part of the quantitative analysis will be cross-sectional.

3.2. Data sources

The sample for analysis, shown in the next section, is the result of the compilation of data collected from financial reports of companies that completed M&A deals in recent years, and that have reported business combinations accounting changes following the adoption of the new FASB's standards. The companies composing the S&P 500 index, effective after the close of 31 December 2004, were the centrepiece of the study, and therefore data has been collected from these companies' financial reports. S&P 500 index includes firms with large capitalization values, listed on both NYSE and NASDAQ. The fact these companies were listed enhanced the odds of involvement in M&A deals, as exchange markets ease the concretization of M&A deals.

In the USA, the Form 10-K is an annual filing which provides a comprehensive overview of the company for the period of a year. 10-K forms are often included in annual reports, although they are formally prepared to comply with the SEC, and the Securities Exchange Act requirements; while annual reports are primarily focused in investors. Since companies have to report material changes as a result of the adoption of new accounting standards, it is therefore possible to collect data directly from annual reports and 10-K forms.[99] The data was collected primarily from the 10-K forms. The SEC Filings and Forms (EDGAR), and the EDGAR Online Pro database, were the main data sources used.[100] Data from annual reports was also examined in order to collect additional information about some companies. The data sources for annual reports were The Annual Reports Service, from Barron's, and several S&P 500 companies' websites.

3.3. Data collection

---

[99] In this paper, "annual report", "Form 10-K", and "annual filling" are interchangeably used.
[100] In some cases the Form 10-K was not available and the Form 10-K405 was examined instead. Like the Form 10-K, the Form 10-K405 is also a SEC filing, but indicates a file violation resulting from the lack of disclosure of insider trading activities from the reporting company. The identification of the form as 10-K405, versus ordinary 10-K, was made by a company's officer or director, and not by SEC officials. Unsurprisingly, it resulted in inconsistent designations by companies. Accordingly, the SEC's Branch of Public Reference discontinued the requirement to designate a filing as a Form 10-K405, effective after 2002, and 10-K405 forms were no longer accepted by the SEC filings system.

Since both SFAS 141 and SFAS 142 became effective during 2001, annual reports and 10-K forms have been examined since fiscal year 2001. Most companies have fiscal years ending in 31 December, or by the end of the year, and therefore the changes in business combinations accounting occurred in 2001 were likely to be disclosed immediately, i.e., from 2002's filings onwards. However, as discussed later in this section, filings up to year 2004 could still refer to 2001's changes in business combinations accounting.

3.3.1. New business combinations accounting standards disclosures

Both new business combinations accounting standards contain detailed provisions concerning disclosures on business combinations and on accounting changes, as shown in paragraphs 51 to 58 of SFAS 141 (Financial Accounting Standards Board, 2001a), and in paragraphs 44 to 47 of SFAS 142 (Financial Accounting Standards Board, 2001b). They are mostly to be presented in the notes to the financial statements. SFAS 142 also provides further guidance on disclosures in its Appendix C, by the means of illustrations. Much of the impacts reported by companies were based in such guidance.

An example of financial reporting disclosure on business combinations' new accounting follows for 3M Company. For the year ended in 31 December 2001, 3M Company, registered as Minnesota Mining and Manufacturing Company, filed the Form 10-K405 in 11 March 2002, as required by the Securities Exchange Act of 1934. By standard, every reporting company devoted a section or specific paragraphs announcing the enforcement of the new business combinations pronouncements. In the first year of SFAS 141 adoption, 3M Company reported (Item 7, 2002):

> "In June 2001, the Financial Accounting Standards Board issued SFAS No. 141, *Business Combinations*. SFAS No. 141 applies to all business combinations with a closing date after June 30, 2001. The most significant

> changes made by SFAS No. 141 are: 1) requiring that the purchase
> method of accounting be used for all business combinations initiated after
> June 30, 2001, and 2) establishing specific criteria for the recognition of
> intangible assets separately from goodwill."

This description resembles a commonplace, as it illustrates the way companies reported

the generic changes in business combinations accounting. Overall, companies reported

the existence of the new business combinations standard, SFAS 141, but no effects

were to be disclosed, as pooling of interest was simply no longer an option. The

adoption of SFAS 141 was therefore absolutely neutral from a financial point of view.

When referring to both SFAS 141 and SFAS 142 it is stated that (Notes to Consolidated

Financial Statements, 3M Company, 2002):

> "These standards permit only prospective application of the new
> accounting; accordingly, adoption of these standards will not affect
> previously reported 3M financial information."

Since pooling of interests had been discontinued, no prospective application was

therefore possible for SAFS 141. Companies simply informed whether they used pooling

method before its elimination. However, a very different scenario was set for SFAS 142.

Like for SFAS 141, companies produced a similar standard description for SFAS 142

(Item 7, 3M Company, 2002):

> "The Financial Accounting Standards Board recently issued Statement
> No. 142, *Goodwill and Other Intangible Assets*, which will be adopted by
> the company effective January 1, 2002. Goodwill and intangible assets
> acquired after June 30, 2001, are subject immediately to the non-
> amortization and amortization provisions of this statement, while existing
> goodwill and other indefinite-lived assets will no longer be amortized
> beginning January 1, 2002. Goodwill will be subject to an impairment test
> at least annually".[101]

---

[101] According to SFAS 142 (paragraph 43, 2001a), goodwill is the excess of cost of an acquired entity over the net
amounts assigned to assets acquired and liabilities assumed in a business combination.

However, a more detailed examination on the accounting changes resulting from SFAS 142 adoption is provided in the notes, as shown in the two paragraphs quoted below (Notes to Consolidated Financial Statements, 3M Company, 2002):

> "SFAS No. 142 primarily addresses the accounting for acquired goodwill and intangible assets (i.e., the post-acquisition accounting). The provisions of SFAS No. 142 will be effective for fiscal years beginning after December 15, 2001. The most significant changes made by SFAS No. 142 are: 1) goodwill and indefinite-lived intangible assets will no longer be amortized; 2) goodwill and indefinite-lived intangible assets will be tested for impairment at least annually (…); and 3) the amortization period of intangible assets with finite lives will no longer be limited to 40 years."

Indeed, further examination of 3M's Form 10-K405 reveals that the focus of business combinations accounting changes is on SFAS 142, as it is clearly assumed that:

> "The principal effect of SFAS No. 142 will be the elimination of goodwill amortization. Amortization of goodwill and indefinite-lived intangible assets in 2001 was $67 million (net income impact of $51 million, or 12 cents per diluted share)".

The paragraph above identifies and illustrates the impact subject to analysis in this section. Since the effects from SFAS 142's adoption are to be measured by the companies, no computation from the researcher is needed. This is an advantage for the researcher, as the risk of a biased data handling is avoided. Any possible computation flaws are therefore responsibility of the reporting companies.

Like its peers, 3M Company was amortising goodwill in wide periods, including the maximum amortisation ceiling. As referred to by 3M Company in its annual report notes, in the first quarter of 2001 three notable business combinations were completed using purchase method. The purchased intangible assets, including goodwill, were being amortised on a straight-line basis over the periods benefited, ranging from 4 to 40 years

(Notes to Consolidated Financial Statements, 3M Company, 2002). As referred in the last quoted paragraph, if SFAS 142 would be adopted in 2001 the relief in losses as a consequence of the nonamortisation of purchased goodwill would be of $51 million alone for 3M Company. This would result in a significant increase of earnings per share in 2001: from $3.58 to $3.70, a net impact of 12 cents. Although 12 cents in $3.58 stand for *only* a 3.35% increase, evidence collected in this research, and to be shown later in this section, suggests the existence of significant higher impacts for most companies in the scope of the adoption of the new business combinations accounting standards.

The positive impact of the elimination of amortisation of acquired goodwill and other intangible assets on earnings was certainly minimized by the recognition of impairment losses, also under SFAS 142.[102] At least for 126 and 40 companies in fiscal years 2002 and 2003, respectively, which have disclosed some type of impaired purchased goodwill and other intangible assets than goodwill, following SFAS 142 adoption. In the universe of S&P 500 index companies, these impairing companies figures represent only around 25% and 8% in total, for 2002 and 2003, respectively.

Taking once again 3M Company as an example of accounting treatment, the impairment tests procedure under SFAS 142 was described in the following way (Note 1, 3M Company, 2003):

---

[102] Under SFAS 141, business combinations companies are required to estimate the fair value of acquired intangible assets in the following manner: first, intangible assets must be categorized by type, such as customer lists, trademarks, patents, software, intellectual property, etc; second, intangible assets with an identifiable remaining useful life must be separated from those with an indefinite useful life. The latter is then classified as goodwill and must be subject to a two-step test for impairment under FASB 142, which companies were required to adopt by January 1, 2002. However, if goodwill and other intangible assets acquired in a transaction for which the acquisition date is after June 30, 2001, but before the date of fully adoption of SFAS 142, these assets are to be reviewed for impairment in accordance with APB Opinion 17, or with SFAS 121, as appropriate, until the date that SAFS 142 is applied in its entirety (Paragraph 51, Financial Accounting Standards Board, 2001b).

Under SFAS 142, the two steps of the goodwill impairment test are (Paragraphs 19-22, Financial Accounting Standards Board, 2001b): first, identifying potential impairments by comparing the fair value of a reporting unit to its carrying amount, including goodwill. Goodwill is not considered impaired as long as the fair value of the unit is greater than its carrying value. The second step is only required if an impairment to goodwill is identified in step one; second, comparing the implied fair market value of goodwill to its carrying amount. If the carrying amount of goodwill exceeds its implied fair market value, an impairment loss is recognized. That loss is equal to the carrying amount of goodwill that is in excess of its implied fair market value, and it must be presented as a separate line item on financial statements.

"Beginning January 1, 2002, goodwill will be tested for impairment annually, and will be tested for impairment between annual tests if an event occurs or circumstances change that would indicate the carrying amount may be impaired. Impairment testing for goodwill is done at a reporting unit level. Reporting units are one level below the business segment level, but can be combined when reporting units within the same segment have similar economic characteristics. 3M, at year-end 2002, had 20 reporting units under the criteria set forth by SFAS No. 142. The vast majority of goodwill relates to and is assigned directly to a specific reporting unit. An impairment loss would generally be recognized when the carrying amount of the reporting unit's net assets exceeds the estimated fair value of the reporting unit. The estimated fair value of a reporting unit is determined using earnings for the reporting unit multiplied by a price/earnings ratio for comparable industry groups, or by using a discounted cash flow analysis."

Although the accounting procedure for impairment testing seemed to be reasonably well described, and despite the multiple business combinations involving 3M Company in the preceding years, including 9 deals in 2002, no impairment charges were recorded for purchased goodwill in 2002 (Note 1, 3M Company, 2003):

"The company completed its assessment of any potential impairment upon adoption of this standard and upon its annual assessment and determined that no impairments existed."

The absence of impairment charges was not an exclusive for purchased goodwill, as it was also extended for other intangible assets with indefinite life, such as patents, tradenames, and others, acquired from an independent party.[103] In neither of the fiscal

---

[103] Bellow is shown the treatment given by 3M Company to purchased intangible assets with an indefinite life (Note 1, 3M Company, 2003):

"Effective January 1, 2002, with the adoption of SFAS No. 142, intangible assets with an indefinite life, namely certain tradenames, are not amortized. Intangible assets with a definite life are amortized on a straight-line basis with estimated useful lives ranging from 2 to 17 years. Indefinite-lived intangible assets will be tested for impairment annually, and will be tested for impairment between annual tests if an event occurs or circumstances change that would indicate that the carrying amount may be impaired. Intangible assets with a definite life are tested for impairment whenever events or circumstances indicate that a carrying amount of an asset (asset group) may not be recoverable. An impairment loss would be recognized when the carrying amount of an asset exceeds the estimated undiscounted cash flows used in determining the fair value of the asset. The amount of the impairment loss to be recorded is calculated by the excess of the assets carrying value over its fair value. Fair value is generally determined using a discounted cash flow analysis. Costs related to internally developed intangible assets are expensed as incurred.".

years examined, from 2001 to 2004, had 3M Company recorded any impairment loss related to SFAS 142's adoption.

For the present paper it would be more relevant to be aware of impairment charges in the first year of adoption of new business combinations accounting standards. As suggested before, overall, despite being considered a "big bath year", impairment losses recorded in 2002 were not as significant as one could expect. There are many possible justifications for this fact, but perhaps two simple reasons may explain reasonably why this happened. First, perhaps the most important reason for the absence of impairment charges was the lack of in-depth guidance regarding the application of impairment tests. It was also an upcoming intense period of accounting regulation changes.[104] Second, conceivably some companies did not have much time to carefully proceed with impairment tests, in order to evaluate any possible impairment losses under SFAS 142. In the case of 3M Company, it was implicitly admitted that no extensive impairment tests were performed in a first stage of SFAS 142's adoption (Notes, 3M Company, 2002):

> "A preliminary review indicated that no impairment existed at December 31, 2001".

However, this discussion is not considered to be relevant to the present research, and therefore only the impact on earnings from the non-amortisation of purchased goodwill and other intangible assets with indefinite life was examined in-depth.

3.3.2. Adoption and disclosure timing of SFAS 142 impacts

---

[104] The accounting changes in early 2000's were not an exclusive from business combinations, as other FASB pronouncements became effective in the same period, such as: SFAS 140, *Accounting for Transfers and Servicing of Financial Assets and Extinguishments of Liabilities a replacement of FASB Statement 125*; SFAS 143, *Accounting for Asset Retirement Obligations*; SFAS 144, *Accounting for the Impairment or Disposal of Long-Lived Assets*, or SFAS 145, *Rescission of FASB Statements No. 4, 44, and 64, Amendment of FASB Statement No. 13, and Technical Corrections*. More accounting standards would be enforced in the upcoming years. Following several scandals that led to major corporate failures, the US Congress passed the Sarbanes-Oxley Act (SOX) of 2002, enacted in 30 July, in order to improve investors' protection from the possibility of fraudulent accounting activities by corporations.

SFAS 142 is the most important of the new business combinations accounting standards for the present research, as the information to be collected from the annual reports is disclosed under its provisions. It is therefore critical to understand the process of disclosure and adoption of SFAS 142 by the companies. A brief chronology follows. After FASB issued the new business combinations accounting standards in June 2001, companies become likely to mention that fact immediately after in their annual reports. However, no impacts had to be disclosed immediately, as companies only needed to compulsorily adopt SFAS 142 provisions from fiscal year 2002 onwards.

Indeed, as SFAS 142 provisions were required to be applied starting with fiscal years beginning after 15 December 2001 (Paragraph 48, Financial Accounting Standards Board, 2001a), and as fiscal year ending in 31 December is the commonest financial reporting period, most S&P 500 companies adopted SFAS 142 immediately in 2002. However, companies with a fiscal year beginning after 31 December 2001 could defer adoption of SFAS 142 for 2003's fiscal year.[105]

Another justification for the immediate adoption of SFAS 142 in 2002 by majority of companies, was that early application was permitted for entities with fiscal years beginning after March 15, 2001, provided that the first interim financial statements would have not been previously issued (Paragraph 48, Financial Accounting Standards Board, 2001a). Finally, it is important to recall that regardless the date of adoption, goodwill and certain intangible assets with an indefinite life acquired after 30 June 2001 would not be amortised, but tested for impairment. This means that in some cases SFAS 142 could have to be implemented in mid-fiscal year. An interesting application example is provided in SFAS 142 (Paragraph 50, Financial Accounting Standards Board, 2001b):

---

[105] It is important to note that when a fiscal year does not coincide with the calendar year, then the calendar year in which the fiscal year ends is used in the shorthand. For example, if a company's fiscal year begins in 1 February 2001, and therefore ends in 31 January 2002, it would be then considered as 2002's fiscal year. This is the case of Wal-Mart Stores Inc., as shown below.

> "an entity with a December 31, 2001 fiscal year-end would be required to initially apply the provisions of this Statement on January 1, 2002; if that entity completed a business combination on October 15, 2001, that gave rise to goodwill, it would not amortize the goodwill acquired in that business combination even though it would continue to amortize until January 1, 2002, goodwill that arose from any business combination completed before July 1, 2001. Intangible assets other than goodwill acquired in a business combination or other transaction for which the date of acquisition is after June 30, 2001, shall be amortized or not amortized in accordance with paragraphs 11–14 and 16 of this Statement."

In terms of disclosure under SFAS 142 provisions, most companies reported impacts on results for the two fiscal years preceding SFAS 142 adoption. It is important to note that companies did not measure the impact on results as a result of SFAS 142 adoption. For the fiscal year of adoption, companies reported the *virtual* impact on previously reported results instead, by the means of adjusted results. The majority of the companies adopted SFAS 142 in fiscal year 2002, and reported accordingly impacts for fiscal years 2000 and 2001.

A reduced number of companies did not report SFAS 142 effects for 2000 and 2001, but disclosed impacts only for the following fiscal years of 2001 and 2002. This was the case of Wal-Mart Stores Inc. Wal-Mart's fiscal year-end is 31 January.[106] According to the Form 10-K filed by Wal-Mart for the fiscal year ended in 31 January 2002 (2002: 23):

> "We will apply the new rules on accounting for goodwill and other intangible assets beginning in the first quarter of fiscal 2003. Application of the nonamortization provisions of the Statement is expected to result in an increase in net income of approximately $250 million for fiscal 2002. Prior to the completion of the second quarter of fiscal 2003, we will

---

[106] The fiscal years information was collected from EDGAR Online Pro database during the period 2004-2005, and do not correspond necessarily to the fiscal years exhibited in the annual reports that were examined in this research. For example, the fiscal year for NVIDIA corp. ended in 25 January. This closing date corresponds to the year 2004. However, the fiscal years in the period of analysis were slightly different, as ending dates were 26, 27, and 28 January, for 2003, 2002, and 2001, respectively. These rolling dates are the consequence of the adoption of a fiscal year that ends always on the same day of the week. In this case, some fiscal years will have 52 weeks, while a few others will have 53. Using Cisco Systems to illustrate the adoption of this particular type of fiscal year, the company announced that commencing with fiscal year 1997, the company's fiscal year would be the 52- or 53-week period ending on the last July's Saturday (Cisco Systems, 1998). The fiscal 1997 was a 52-week fiscal year which ended in 26 July 1997. The fiscal 1998 was also a 52-week fiscal year, and therefore ended in 25 July 1998. The fiscal 1999 was however a 53-week fiscal year, in order to match with an ending in the last Saturday of July which, in 1999, corresponded to 31 July.

complete a transitional impairment review for goodwill and indefinite lived intangible assets as of the date of adoption. Subsequently, we will perform similar impairment reviews on an annual basis. Management does not believe that the adoption of the impairment review provisions of the statement will have a material effect on the earnings and financial position of the Company."

It is interesting to observe that not only Wal-Mart supposedly delayed any effective decision on impairment charges under SFAS 142 to 2003's fiscal year, avoiding the so-called "big bath earnings management" occurred in 2002, as it has also reported the impact on results for the first time only in 2002. This was due to the fact that, despite some companies were due to adopt SFAS 142 immediately in 2002, other companies were required to adopt SFAS 142 only in 2003. Indeed, when Wal-Mart filed the Form 10-K for the year ended in January 2002, the new business combinations accounting rules were already enforced, but SFAS 142 adoption was not yet effective, as only for the fiscal year ended in January 2003 was Wal-Mart required to report SFAS 142 effects.

Apart from companies that had to adopt SFAS 142 in fiscal years 2002 and 2003, there was also the case of companies that could be entitled to adopt the new accounting standard earlier. The earliest adoption possible of SFAS 142 was for companies with a fiscal year beginning in 15 March 2001, i.e., ending in 14 March 2002. However, as stated in SFAS 142 (Paragraph 48, Financial Accounting Standards Board, 2001b):

"In all cases, the provisions of this Statement shall be initially applied at the beginning of a fiscal year. Retroactive application is not permitted.".

Apart some exceptions, not applicable in this case, this provision means that Wal-Mart could only adopt SFAS 142 in its fiscal year beginning in 1 February 2002. It cannot be then argued that Wal-Mart deferred SFAS 142 adoption. As Wal-Mart could only adopt

SFAS 142 in fiscal year 2003, is has therefore disclosed information on impacts for the fiscal years ending in 2001 and 2002.

For a better understanding of this reasoning, detailed information on SFAS 142 timings of adoption and disclosure follows. Companies with fiscal years beginning between 15 March 2001 and 14 December 2001 could adopt SFAS 142 earlier, provided that the first interim financial statements would have not been previously issued. Since SFAS 142 was to be adopted unrestrictedly only from the fiscal year beginning in 15 December 2001, early adoption can be considered as optional.

In terms of year of adoption, all companies had to adopt SFAS 142 in fiscal years 2002 or 2003. Companies with fiscal years ending from 14 March 2002 to 31 December 2002, could have adopted SFAS 142 for 2002's fiscal year. Most of these companies disclosed impacts on precedent reported results for the two preceding fiscal years, i.e., 2000 and 2001. However, some disclosed impacts only for the preceding fiscal year of 2001.

Companies with fiscal years beginning from 2 January 2002 to 14 December 2002, had to adopt SFAS 142, as any deferral would constitute a violation to SFAS 142 implementation provisions. It can be then concluded that all companies had to adopt SFAS 142 at least during fiscal year 2003, in case they did not adopted it earlier. Most of companies that adopted SFAS 142 in fiscal year 2003 have disclosed impacts on reported results for the two preceding fiscal years, i.e., 2001 and 2002. However, some companies disclosed impacts only for the preceding fiscal year of 2002.

Finally, all companies with fiscal years ending after 13 December 2003 were due to adopted already SFAS 142, as its latest adoption was required for all companies with fiscal years beginning after 14 December 2002. If a company would adopt SFAS 142

from the fiscal year ending in 14 December 2003 onwards, it would be then violating SFAS 142's adoption provisions.

In resume, companies with fiscal years beginning between 2 January 2002 and 14 March 2002 could only adopt SFAS 142 in fiscal year 2003, while companies with fiscal years starting between 15 December 2001 and 1 January 2002 had to adopt SFAS 142 in fiscal year 2002. Companies with fiscal years beginning between 15 March 2001 and 14 December 2001, and between 15 March 2002 and 14 December 2002, could have adopted SFAS 142 in 2002 or 2003, respectively.

It is therefore possible to make the following generalization: during the period of adoption of SFAS 142, companies with fiscal years beginning between 2 January and 14 March had to adopt SFAS 142 in fiscal year 2003, while companies with fiscal years starting between 15 December and 1 January had to adopt SFAS 142 in fiscal year 2002. Companies with fiscal years beginning between 15 March and 14 December could adopt SFAS 142 in 2002, provided that the first interim financial statements would have not been previously issued, or a fiscal year later, in 2003. In case the company had to adopt SFAS 142 during mid-fiscal year, as required by paragraph 50 of SFAS 142, this generalization does not apply.

3.3.3. Impact measurement

Companies reporting under SFAS 142 have disclosed diverse information about the impacts from the nonamortisation of acquired goodwill and indefinite-lived intangible assets. They have also included supplemental statements of income with information about SFAS 142 impacts on both reported and adjusted bases. The measurement of SFAS 142 impacts on previously reported results, included information about the amount of acquired goodwill and indefinite-lived intangible assets not any longer subject to

amortisation, and pro-forma figures for net income (or net losses), had the new accounting standard been in effect for previous fiscal years.

One of the most important figures that companies had to disclose under SFAS 142 was the impact on EPS. As a major indicator of a company's profitability, the EPS assumes particular importance in the USA where it is highly regarded. In fact, despite the immense variety of indicators used in financial analysis, EPS is still considered a leading indicator for evaluating share prices.

The FASB requires companies' financial statements to report EPS for each of the major categories of the income statement: continuing operations, discontinued operations, extraordinary items, and net income (Financial Accounting Standards Board, 1997). In order to ensure the homogeneity of the sample, only comprehensive net income figures were used.

SFAS 128, *Earnings per Share*, specifies the computation, presentation, and disclosure requirements for EPS in the USA. Under SFAS 128, two forms of EPS are required to be reported: basic and diluted. This requirement was also followed in SFAS 142, as shown in its Appendix C (paragraph C5, Financial Accounting Standards Board, 2001b).

Basic EPS is computed by dividing income available to common stockholders, in the numerator, by the weighted-average number of common shares outstanding, in the denominator (paragraph 8, Financial Accounting Standards Board, 1997).

The diluted EPS expands on basic EPS by including the effect of all dilutive potential outstanding common shares. Basic and diluted EPS are therefore similarly computed. However, in diluted EPS computation, the denominator is increased in order to include the number of additional common shares that would have been outstanding if the dilutive

potential common shares had been issued (paragraph 11, Financial Accounting Standards Board, 1997).

Diluted EPS is a more consistent indicator than basic EPS. Additionally, while some companies did not report SFAS 142 impact on basic EPS, they all however reported the effect on diluted EPS. Therefore, diluted EPS has been taken in this research as a proxy for measuring the impact of SFAS 142 on reported earnings.

3.3.4. Resume of data collection procedure

As SEC filings were the main data source, a note on its timing follows. In terms of 10-K and 10-K405 forms, considering they need to be filed up to 3 months after the fiscal year has ended, companies with fiscal years ending from 14 March 2002 to 30 September 2002 were due to have their filings prepared in 2002. As for companies with fiscal years ending between 31 October 2002 and 30 September 2003, the 10-K forms had to be filed until the end of 2003. Finally, companies with fiscal years ending after 31 October 2003 were due to file the 10-K forms only in 2004.

In order to ensure that all companies reporting SFAS 142 effects could be identified, the SEC filings from 2001 to 2004 were examined. Although companies did not adopt SFAS 142 in fiscal year 2001, the filings were examined in order to analyse earlier disclosures related to the new business combinations standards. This examination also intended to capture any possible particular or abnormal disclosure. The 2004 filings were also examined, not only to collect information about companies that had to adopt SFAS 142 until the fiscal year ending in 13 December 2003, which had to file the Form 10-K until in the first quarter of 2004; but also to ensure that companies potentially delayed in reporting on new business combinations accounting could still be included in the sample.

This additional data verification has revealed to be important as some early disclosures on SFAS 142 would be later revised by a few reporting companies. Whereas the reported information of a more recent Form 10-K, or annual report, conflicted with similar information reported in previous years, the newest information has been the one selected for the final sample. Therefore, for most companies, the search for SFAS 142 effects started with the examination of 2004's filings, even knowing in advance that almost all companies reported such effects in 2002 and 2003 filings.

Finally, the period of 2001-2004 was fertile in financial reporting restatements. Accordingly, some companies filed later amendments, using the Form 10-K/A. In some cases, a half dozen of amendments were filed by a single company during the period 2001-2004. It cannot be assured that every amendment filed has been verified. Additionally, despite similarities in financial reporting, some companies reported SFAS 142 effects in slightly different ways, forcing in a few occasions to rely on personal judgement in order to harmonize the information made available in annual reports by all companies.[107]

3.4. SFAS 142 impacts sample

As discussed before, the sample for analysis is the result of the congregation of data collected from financial reports of companies that completed M&A deals in recent years, and that have reported business combinations accounting changes following the adoption of the new FASB's standards. The annual filings from 2001 to 2004 of the 500 companies that composed the S&P 500 index in 2004 were examined, as this index is considered to be an excellent proxy for the corporate environment were a significant part

---

[107] Any inaccuracy from the data collecting process that may be reflected in the annual reports sample is exclusive responsibility of the author.

of the M&A activity is placed. The use of S&P 500 index also ensures a good coverage for the most significant industries in the USA.

[*Please insert Figure 1 here*]

As shown in Fig. 1, the corporate sectors included in S&P 500 index are quite diversified, being most industries well-weighted. By the end of 2004, financials and the IT industry represented about one-third of S&P 500 companies. Together with consumer discretionary companies, IT and financials accounted for half of the companies in the index.

Following the examination of the 500 S&P's companies, it was been found that more than half of the companies disclosed impacts in the scope of the adoption of SFAS 142. More precisely, at least 257 companies measured and disclosed impacts on results as if SFAS 142 would have been previously adopted. In addition, another 219 companies referred adoption of SFAS 142, but did not provide any measurement and details of the impact. Some other 4 companies referred the effectiveness of SFAS 142, but did not clarify whether they were entitled for adoption. In resume, only 24 companies did not assume clearly SFAS 142 adoption.

The majority of the companies disclosed impacts for 2000 and 2001, regardless different fiscal years' endings. However, as referred before, a company with a fiscal year ending between 14 March and 13 December could have adopted SFAS 142 only in 2003. In case of adoption in fiscal year 2003, it was then natural to report impacts for 2001 and 2002.[108] As a result of this myriad of possibilities, the sample comprised 257 companies with the following reporting status:

i) 222 companies disclosed information for both fiscal years 2000 and 2001;

ii) 10 companies disclosed information only for fiscal year 2001;

iii) 24 companies disclosed information for both 2001 and 2002; and

iv) 1 company disclosed information only for fiscal year 2002.[109]

---

[108] However, a few companies disclosing adoption of SFAS 142 in 2003 reported impacts for 2000 and 2001.
[109] A small group of retailers, including Kohl's Corporation, The May Department Stores Company, and The Kroger Co., adopted SFAS 142 on the fiscal year starting in 3 February 2002. According to them, this adoption was made in fiscal year 2002, and therefore the impacts from SFAS 142 were disclosed for 2000 and 2001. According to the theoretical framework presented in this research, a 2003 fiscal year-end reporting corresponds to fiscal year 2003, not 2002. This framework matches with the views of the remaining companies in the sample. Therefore, had these retailers following the standard views on fiscal year definition, and they would have disclosed impacts for years 2001 and 2002, as if they had adopted SFAS 142 in fiscal year 2003. As this issue is irrelevant for the constitution of the final sample used in this

It was already justified why companies reported SFAS 142 effects in different years. Regardless the year of reporting, what matters for the present research is the homogenised impact on the two fiscal years preceding SFAS 142 adoption. As the large majority of the companies examined, 222 in 257, reported income figures for 2000 and 2001 together with adjusted pro-forma information as if the accounting change had been already in effect, these two fiscal years were taken as a reference for the final sample. This assumption means that data in the final sample referred to 2001 is a proxy for the impacts on the fiscal year preceding SFAS 142 adoption, regardless the effective year of adoption by the companies. Similarly, sample data for 2000 is a proxy for the impacts on the second fiscal year preceding SFAS 142 adoption.

In order to homogenise the reporting periods in the sample, the data from the company presenting information only to 2002 (iv) was considered as being referred to 2001; while data for the 24 companies that reported impacts for fiscal years 2001 and 2002 (iii), has been considered as for years 2000 and 2001, respectively. As a result of this standardization, it is implicit that all companies adopted SFAS 142 in fiscal year 2002, despite this not being true for 25 of the 257 companies included in the final sample.

The final sample is therefore composed by 257 companies, contributing with 503 observations, 246 for 2000, and 257 for 2001. The weight by industry for the 257 companies included in the sample is shown in Fig. 2.

[*Please insert Figure 2 here*]

---

research, it was decided to keep these companies in the group of companies reporting impacts for 2000 and 2001.

Interestingly, the majority of companies impacted by SFAS 142 were from IT industry, with 18.8% of the total sample. Financials ranked third, and together with IT and consumer discretionary they sum for around half of the companies in the sample.

3.5. Basic descriptive statistics and analysis

In terms of global figures for the sample companies, in 2000, the 246 companies reported an average net income of 897.4 millions in dollars value. In average, had SFAS 142 been made effective in 2000, the same companies would report 968.9 millions of net income, a 7.9% increase. In terms of total values for 2000, the 246 companies reported $220.7 thousand millions of net income and would report an adjusted $238.3 thousand millions had SFAS 142 been adopted, as net amortisation of purchased goodwill totalling $17.1 thousand millions, and amortisation of other purchased intangible assets than goodwill of $474 millions, would be discontinued, and consequently added back to reported income. Had SFAS 142 been adopted in fiscal year 2000 and the net income of the 246 companies would be therefore increased in $17.5 thousand millions.

In a similar analysis for 2001, the 257 companies reported an average net income of $406.6 millions, a 54.6% decrease when compared to 2000. As discussed earlier in this paper, the economic climate changed in the beginning of the 2000's, so this sharp decrease in results can be considered as normal. Had SFAS 142 been made effective in 2001, and the 257 companies would report $542.3 millions of net income in average, a 33.3% increase. In terms of global figures for 2001, the 257 companies reported $103.7 thousand millions of net income, and disclosed a pro-forma net income of $138.3 thousand millions, as net acquired goodwill amortisation of $32.9 thousand millions, and amortisation of $1.65 thousand millions related to other purchased intangible assets than goodwill, such as indefinite-lived tradenames, or workforce intangible, would be added back. Therefore, had SFAS 142 been adopted in fiscal year 2001, and the net income of

the 257 companies would be increased by one-third. In face of a period of sharply falling earnings, the immediate adoption in 2001 of SFAS 142 would be certainly welcomed by companies which were amortising purchased goodwill and other intangible assets. If no impairment losses would be recorded, the adoption of SFAS 142, by the means of nonamortisation of purchased goodwill and other intangible assets, would represent a *bonus* of $34.6 thousand millions in earnings for the 257 companies examined.

3.6. Impact on diluted EPS

Since companies had to disclose the *virtual* impact on EPS for the immediate fiscal years before SFAS 142 adoption, and being EPS a powerful and harmonized indicator, an in-depth analysis focused on diluted EPS follows.

As disclosed pro-forma by 246 companies in 2000, the adjusted diluted net income per share was in average 20.7% superior to the diluted net income as reported.[110] Had SFAS 142 been adopted in fiscal year 2001, and the reported net income of the 257 companies examined would increase 29.6% in average.

Some companies reported a zero impact on reported EPS. More precisely, 7 companies in 2000, and 3 in 2001. Had these companies being excluded from the sample, and the average impact of SFAS 142 adoption on diluted EPS would be of 21.3% and 30%, for 2000 and 2001, respectively. The average impacts on diluted EPS are very much meaningful by all means.

---

[110] The growth ratio for diluted EPS is expressed as a percentage, and shows the relative growth of diluted EPS over the last reporting period. In some cases, the ratio had to be computed using negative values. In order to allow proper computations of growth using negative EPS values, the following formula with absolute values in the denominator has been employed:

$$\frac{current\ year's\ EPS - previous\ year's\ EPS}{\left|previous\ year's\ EPS\right|} \times 100$$

The diluted EPS sample median was 7.18% for 2000, and 9.52% for 2001. The high discrepancy of the median versus average, 7.18% vs. 20.7%, and 9.52% vs. 29.6%, suggests the existence of outliers biasing the sample average. The impact of companies reporting zero impact is not significant, as revealed by the minor differences between the average percentages for the whole sample versus sample excluded from zero values. Therefore, outliers are not minimum, but maximum values.

Indeed, a substantial number of companies disclosed impressive impacts on diluted EPS, had SFAS 142 been adopted. The maximum impact on diluted EPS reported in 2000 was 4.85 times, or 385%. A total of 10 companies disclosed adjusted diluted EPS with increases of 100% or more. For 5 companies the impact on reported diluted EPS was at least 200%. The sample standard deviation was 0.47.

The impact of SFAS 142 on 2001's earnings would be even more expressive. The maximum impact disclosed was 7.6(6) times the reported diluted EPS, an increase of 666%. 12 companies reported impacts of 100% or more, 6 reported increases of at least 200%, and similarly, 4 reported 400%, and 3, 500% or more. Unsurprisingly, the dispersion of values was higher than in 2000, and therefore the standard deviation was also higher, 0.77.

A final indication about the significant weight of the outliers follows. For 2000, 48 companies reported differences between adjusted diluted EPS and reported diluted EPS superior to the average of the 246 observations: 20.7%. In 2001, the impact for 51 companies was superior to the average impact for the 257 sampled companies: 29.6%.

4. Cross-sectional analysis

Since the analysis from the survey suggested the existence of significant effects of the new business combinations accounting standards on IT industry, and as the sample for

annual reports comprises the same 10 main sectors of activity as for the questionnaires' sample, allowing direct data triangulation, it is therefore of interest to develop a cross-sectional analysis. The cross-sectional data for analysis is shown in Table 1.

[*Please insert Table 1 here*]

Table 1 exhibits the weighted average of purchased goodwill and other intangible assets that would be added back for 2000 and 2001, had SFAS 142 being adopted. It is possible to observe that companies from industries such as energy, $26.3 millions, health care, $35.4 millions, and utilities, $35.9 millions, have the lowest average amounts of goodwill and other intangible assets, while, conversely, IT, $144.4 millions, telecommunication services, $122.4 millions, and consumer discretionary, $117.5 millions, exhibit the highest amounts, which are significantly expressive for 2001. In fact, the amounts of goodwill and other intangible assets rose for every industry from 2000 to 2001, but this increase was particularly significant for the companies from the 3 industries with the highest amounts of purchased intangible assets that could be added back under SFAS 142.

In terms of diluted EPS in 2000, utilities recorded the lowest impact, 6.29%. Companies from consumer staples, telecommunication services, and energy, with impacts of a little above 10%, were also in the group of the less possibly impacted by SFAS 142. On the opposite side, materials, 31.94%, health care, 30.22%, and industrials 28.09%, topped the ranking of the industries with the highest impacts.

Overall, impacts on diluted EPS were higher for 2001. Only consumer staples, 8.82%, and utilities, 12.27%, did not exceed by far impacts around 10%. The companies from these 2 sectors were also the ones with the lowest impacts for 2000-2001: 9.5%, and 9.29%, respectively. The highest impacts in 2001 were recorded for IT, 66.64%, industrials, 34.85%, and consumer discretionary, 30.01%. The companies from these 3

industries have also recorded the highest average impacts on diluted EPS for 2000-2001, with 42.48%, 31.53%, and 27.18%, respectively.

Considering that the impacts from 2000 and 2001 can be extrapolated for 2002 onwards, seems justifiable to argue that companies from IT, consumer discretionary, and industrials, were the most affected by SFAS 142 adoption. The overall evidence also indicates that IT companies were the most impacted by SFAS 142. Indeed, not only they had the highest average values of purchased goodwill and other intangibles subject to nonamortisation in 2001, as they were also the ones suffering the most significant impacts on diluted EPS.

5. Caveats

Evidence shown in this paper was not subject to formal statistical testing and validation, and therefore conclusions need to be drawn carefully. An example of the possible consequences of lack of control for statistical assumptions follows. The company with the highest impact on diluted EPS in the sample is from the IT industry, 666% in 2001. Despite the sizeable number of IT companies in the sample, 48 in 2001, had this outlier been removed and the average diluted EPS in 2001 would have decrease from 66.64% to 53.88%. Similarly, the average value of purchased goodwill and other intangibles would decrease from $201.6 millions to $201.4 millions. An insignificant impact in this case, however. Overall, the elimination of this outlier, or unusual observation, does not change fundamentally any of the analyses drawn before. However, since it reduces significantly the impact on diluted EPS, it therefore smoothes the prevalence of IT overthe remaining industries in what concerns to SFAS 142 effects.

Other major outliers, i.e. impacts over 200% on diluted EPS in 2000 and 2001, are included in health care, financials, industrials, and IT industries.[111] Although these industries are among the ones with higher number of observations, the corresponding figures and findings need however to be regarded with due care, particularly for single yearly analyses.

Weighted average figures including both 2000 and 2001 are more robust, as the potential effect from possible outliers is more diluted, providing therefore more reliable analyses. Taking again IT industry as an example, had the same outlier been removed and, for the period 2000-2001, the weighted average diluted EPS would be reduced from 42.48% to 35.61%, while the weighted average value for goodwill and intangibles added back would have an imperceptible decrease from 144.42 millions to 144.38 millions.

Nevertheless, although not shown, some sensitivity analysis were performed to ensure that the findings presented in this paper were not significantly biased, and also to minimize the lack of statistical testing and validation.

6. Discussion of results and suggestions for further research

From the analysis of 10-K forms and annual reports it was possible to find that the changes in business combinations accounting resulted in significant impacts in the financial reporting. Had SFAS 142 been made effective in 2000 and diluted EPS from S&P 500 companies would have increased 20.7% in average. Similarly, adoption of SFAS 142 in fiscal year 2001 would produce an even more significant average increase of 29.6% in diluted EPS. These positive effects are sizeable enough to do not be neglectful of. Moreover, such impacts are materialised in billions of dollars in purchased goodwill and other intangible assets not to be amortised that, if not subject to significant

---

[111] Outliers' threshold set arbitrarily.

impairment losses, mean meaningful earnings increases simply as a result of a technical adjustment, i.e., a change in GAAP.

To the best of the knowledge of the author of this paper, this finding is unique in existing literature. However, some authors anticipated or estimated similar impacts under different, but related circumstances. For example, Ayers et al. (2000), using a sample of pooling companies, estimated that EPS would have been considerably lower if purchased method had been used. By the time Ayers et al.' study was made, purchased goodwill and other intangible assts were still amortised over a maximum period of 40 years. This is the reason why the earnings that would decrease in case pooling method would be eliminated.

The Ayers et al. paper is also interesting because, despite a natural *opposite* finding, it brings a *comparable* measurement. In Ayers et al. study, assuming a 10-year amortisation period, the decrease in EPS would be from 8.3% in financial services, up to 42% in food, textile, and chemicals industries. Assuming a 40-year amortisation period, EPS would be reduced from 2.2% to 15.7%, in financial services and in the hotel and other services industries, respectively.

As FASB dropped the initial proposal on replacing a 20-year amortisation period for impairment tests, it has reversed entirely the impact on earnings, in a scenario of absence of impairment losses. Comparing the initial FASB's proposal with the final provisions of SFAS 142, from possible losses over 15% in some industries, to average increases in earnings of more than 20%.

Another interesting outcome from the evidence shown in this paper relates with the big bath earnings management occurred in 2002. It is seems arguable that the replacement of amortisation of acquired goodwill and other intangible assets with definite life by

impairment tests may have eased the recognition of impairment losses immediately upon initial adoption of SFAS 142. Indeed, the positive impact from nonamortisation of goodwill and other intangible assets has diluted, in some cases significantly, the negative impact on corporate earnings of impairing companies. A finding that certainly deserves further examination together with new evidence that continues to emerge from research on SFAS 142 effects.

The evidence collected from the annual reports of S&P 500 companies also corroborates the findings of literature pre-pooling of interests elimination, signalling a possible impact of the accounting changes on M&A activity in IT industry. This strand of literature expressed public concerns from the IT sector about the proposed elimination of pooling of interests (see e.g. King, 2000; King & Kelly, 2000; *Prepared Testimony of Mr. Dennis Powell Vice President and Corporate Controller Cisco Systems*, 2000). Indeed, from the cross-sectional analysis shown in this paper, it is suggested that IT industry may have suffered some impacts from the changes in the accounting regulation. Whether such effects were enough to impact M&A activity on IT industry is not definitive and therefore offers an additional opportunity for further research.

Utilities	23.6	48.1	6.29	12.27	9.29

[†] Weighted average from purchased goodwill, and other intangible assets than goodwill averages. The number of observations used for computing the goodwill added back average corresponds to the number of observations used for computing the impact on diluted EPS average. The number of observations used for computing the other intangible assets than goodwill average is not shown.

[‡] Weighted average for 2000 and 2001's average impacts on diluted EPS.

3.2 Management Accounting

TRANSFER PRICING IN SERVICE ORGANISATIONS: AN AUSTRALIAN PERSPECTIVE

Bülend Terzioğlu, Australian Catholic University
Robert Inglis , RMIT University, Melbourne
Robert Clift, RMIT University, Melbourne

The purpose of this paper is to report the results of a survey of transfer pricing practices of service organisations in Australia. A unique feature of the present research is that, it is designed to examine the relationship between transfer price and the perceived value by the internal customer which has not been investigated in prior research.

Using survey responses from eighty service organizations and thirteen face-to-face interviews held with corporate staff and divisional managers, it is established that cost-based transfer pricing is the most widely practiced method in service industries and there is no significant association between transfer price and internal customer perceived value.

Key words: Transfer pricing; services; value

Introduction

Pricing for both external and internal customers is one of most contentious areas of industry practice and academic research. Price determination is still the most inconspicuous, secretive, sacrosanct, and least rational of the marketing strategy components (Morris and Fuller, 1989). According to Monroe and Cox (2001), the data relating to how companies go about pricing suggest that many companies make pricing decisions and changes in pricing policy without an established process for managing the pricing activity. As a result, it is concluded that most companies do not even have a serious pricing strategy and do not conduct pricing research to develop an appropriate strategy. Limited findings to date (e.g., Emmanuel and Mehafdi, 1994; Cooper and Slagmulder, 1998) suggest that transfer prices are also determined in an ad hoc fashion.

Domestic transfer price. Considerable research has investigated transfer pricing for multinationals. Particularly since the early 1990s, the transfer pricing literature displays a noticeable lack of focus on domestic transfer pricing issues. Major studies on domestic transfer pricing include Livesey (1967) and Piper (1969), who investigated the bases of internal pricing and the extent of divisional freedom, respectively. With reference to the rather casual approach adopted by firms documented in the literature, Emmanuel and Mehafdi (1994) question whether transfer price does in any way affect the value received by the internal buyer. Establishing an accurate transfer pricing system is a necessary first step which should be supplemented by intra-organisational cost management systems and micro-profit centres (Cooper and Slagmulder, 1998). The issue of transfer pricing is important for organisations because transfer pricing practices not only affect economic decisions, but also impinge on corporate performance.

If the basis of underlying transfer prices is inaccurate, the subsequent decisions regarding the allocation of resources are also likely to be flawed, potentially leading to some efficient units being closed while less efficient operations are expanded (Ward, 1993).

Interplay between transfer price and internal customer perceived value. For the reason that they pay for the final good or service, and thus influence an organisation's revenues, organizations are often tempted to give precedence to the satisfaction of external customer at the expense of internal customers. The emergence of the notion of 'internal customer' is rather recent. As such, the literature affords relatively greater attention to external customers. Internal customer perceived value is defined as the internal customer's overall assessment of what is received and what is given (Zeithaml, 1988). It is argued that the inability of an organisation to create value for internal units may restrict its ability to create value for external customers. In recognition of the growing importance of internal customers, organisations are now encouraged to focus on internal processes and aim to deliver value to their internal customers (Naumann, 1995). Understanding

what buyers value within a given offering, creating value for them, and then managing it over time have long been recognised as essential elements of every market-orientated firm's core business strategy (Slater and Narver, 1998). Zeithaml (1988) points out that the buyers are concerned with the costs of obtaining the perceived benefits because they typically compare costs and benefits before they make purchase decisions. As internal services increase, among other things, new questions such as 'how do we assess or price their value' would arise (Mills and Ungson, 2001).

Although many researchers agree that external customers today are strongly value- orientated (Heskett *et al*., 1994; Parasuraman, 1997), it is not yet known if value for internal customers is deemed equally important or if the internal price charged between divisions does influence the value received by the internal customer. Gronroos (1981) suggests that organisational units strive to provide their external customers with better performance, lower costs and other benefits of value, and adds that these units should also provide superior service to their internal customers for similar reasons.

Transfer pricing of services. Services represent around 25-30 percent of world trade, and are growing at a rate faster than trade in manufactured goods. In addition, services are the largest component of developed countries' gross domestic product (GDP) accounting for approximately two-thirds to three-quarters of the GDP. In Australia, the services sector generates almost 80 percent of gross domestic product (GDP). Howell and Soucy (1990) indicate that services have become a more significant part of companies' competitive advantage and cost structure, and therefore, management must respond to service pricing issues. Traditionally management accounting systems were developed for goods because services have traditionally been seen as a small part of the total problem solution offered to customers. Owing to additional measurement difficulties, transfer pricing in service organisations is complex and challenging than

manufacturing organisations. In the accounting literature, only a few studies (e.g., Tewes, 1976; Lucien, 1979; Owens, 1982; Drury, 1994; Oyelere and Turner, 2000) have investigated transfer pricing in services. Historically, services are transferred at cost or at a mandated market price equivalent to standard cost plus mark-up (Keegan and Howard, 1988).

Cooper and Slagmulder (1998) argue that many firms allocate support costs to the operating divisions using a 'peanut butter' approach that spreads these costs in arbitrary ways.

This arbitrary approach leads to low accuracy and zero transparency for these costs which then give rise to dissatisfaction and often bloated central services because the operating units are unable to discipline central services adequately. As Keegan and Howard (1988) point out, in the increasingly service-oriented business world, most companies encounter significant hurdles in applying transfer pricing to services, and state that transfer pricing in service organisations is complex and challenging. Extant literature on Australian industries encompasses Chenhall (1979) who surveyed divisionalised companies in Australia, Hilton (1981) who examined transfer pricing policies used by Australian manufacturing firms, Jaye and Blayney (1991) who investigated cost and management accounting practices in Australian manufacturing companies, Chan (1998) who investigated the role of culture and motives in transfer pricing negotiations between U.S. and Australian organizations and Perera *et al*. (2003) who investigated the diffusion of transfer pricing in a government trading enterprise as it moved from protected monopolistic status to commercialisation. Given that the examination of the literature suggests that pricing practices of businesses generally lack sound analysis, deciding what price to charge for various goods and services transferred by one organisational unit to another in the same company is probably one of the most complex issues confronting managers. World-wide, the present knowledge on transfer pricing practices in service organisations is patchy. In Australia, the gap in the literature for a transfer pricing survey in Australia is evident.

This paper is organised as follows: The first section describes the research design and methodology. The second section involves discussion of findings vis-à-vis the earlier findings in the literature. Conclusion is presented in section three. Limitations are outlined in section four, and finally future research directions are summarised in section five.

1. Research design and methodology

Sample. The population consisted of divisionalised service firms operating in transportation and storage, telecommunications, healthcare services, finance and insurance and property and business services sectors in Australia. Databases of the Australian Stock Exchange, Australian Financial Conference, Australian Prudential Regulatory Authority, Advertising Federation of Australia, Insurance Council of Australia and Business Review Weekly 'The Top 500 companies" were used and a sample of 285 divisionalised service firms was drawn using the stratified sampling method.

Data collection. The data for this research were collected by means of thirteen semi-structured interviews and survey questionnaires administered on 285 service organizations. Face-to-face interviews were conducted with managers both at corporate and managerial level. Ferreira and Merchant (1992) report that transfer pricing is a sensitive topic and the use of one-to-one interviews reduces response bias. With a view to eliminating bias and error, every effort was made to avoid leading questions, and not to deviate from the written questions. To address the interrogation error, questions were phrased in a uniform fashion. A digital recorder was used to record interviews. In order to fully capture the spirit of the interviews, in addition to transcribing interviews from an oral to a written mode, necessary care was exercised to include pauses, repetitions, tone of voice, etc.

Finally, to eliminate any recording errors, transcriptions were checked for context and content accuracy prior to data analysis. Information gathering via survey questionnaire was carried out at two levels: (1) corporate; and (2) division. Much of the prior empirical research on transfer pricing has been done with firm-level surveys (e.g., Tang, 1979; Vancil, 1979; Borkowski, 1990). Colbert and Spicer (1995) conclude that such studies resulted in limited understanding and insights because they were directed at the level of the firm as a whole rather than at the divisional level where internal transfers actually take place. Constructs were developed using Churchill's (1979) guidelines.

The questionnaire was developed based on a thorough review of the literature and feedback from the reviewers. Responses to scales that were designed to capture value dimensions were made on 5-point Likert scales anchored by strongly disagree and strongly agree at the end points 1 and 5, respectively. Because of the exploratory nature of the current research, interview and questionnaire questions were drawn largely from the extant literature with a particular emphasis on the works of Parasuraman *et al*. (1988), Sweeney and Soutar (2001) and Emmanuel and Mehafdi (1994).

Prior to mailing, the questionnaire was pre-tested on eight academics two of whom had extensive top level relevant industry experience. In the light of their feedback, appropriate revisions were made. The questionnaire was accompanied by a letter describing the research and its purposes, soliciting participation and assuring respondents' anonymity. A reply-paid envelope was provided for returning the completed questionnaires. A two-part questionnaire (one to be filled by corporate staff and the other by divisional managers) was addressed and mailed to the Chief Executive Officer or Manager of Human Resources as the case may be.

The addressee was requested to pass on the part of the questionnaire designed for the divisional management to a divisional manager of his/her choosing within their organisation with the appropriate knowledge.

Following Phillips (1981) who reports that high-level managers provide more reliable information on organisational phenomena than do lower ranking managers, questionnaire directed to corporate staff solicited answers to questions of general and strategic nature. Questionnaire designed for divisional manager's completion contained questions relevant to intra-departmental exchange of services.

In conclusion, the "benefits" construct is designed to encompass assurance, responsiveness, reliability, empathy, tangibles, flexibility and innovation and alternate solutions and customization and "sacrifice" construct includes price, time, effort and energy, and psychic costs. Two waves of mail surveys were sent four weeks apart

To assess non-response bias, the responses received from the first mailing were compared to those responses received after the second mailing using a Mann-Whitney test, and no significant differences were detected between the two waves among the studied variables suggesting that non-response bias is not evident. For missing data analysis, the listwise deletion option was employed

2. Discussion of findings

Profile of respondents. A total of 80 usable responses were available for analysis representing a response rate of 28.07 percent. The breakdown of respondents is shown in Table 1.

Table 1

Profile of respondents

	Survey Questionnaire		Interviews held	
Service categories	Usable response	%	Number of firms interviewed	Number of interviews conducted
Transportation and storage	12	15.0	1	1
Telecommunications	8	10.0	2	5
Healthcare services	7	8.7	1	1
Finance and insurance	30	37.5	3	3
Property and business services	23	28.8	3	3
TOTAL	80	100.0	10	13

Fifty-five percent of respondents had an annual turnover of AUD 80 million and 24% had an annual turnover of AUD 40-80 million, and the remainder had a turnover of less that $40 million.

Objectives of transfer pricing. Transfer pricing policies generally aim to achieve goal congruence (Abdallah, 1989). It is argued that unless the company acknowledges the importance of internal customers, these internal intermediaries may have different goals and, as a consequence, employees involved in the internal service delivery, even those who wish to be good stewards, may inadvertently set goals that would be different from those set if information flowed perfectly (Evans, 1975). Ease of understanding is the most important objective of the transfer pricing system followed by optimal pricing and goal congruence (Table 2).

Table 2

Objectives of transfer pricing ranked by importance

Objectives of transfer pricing	Mean	Standard deviation
Ease of understanding	1.8846	1.12793
Optimal pricing	2.0390	1.49949
Goal congruence	2.3056	1.69206
Divisional evaluation	2.4342	1.65195
Managerial motivation	2.9697	1.57841
Greater divisional autonomy	3.1493	0.94153

1=Very important, 5= Not important

Almost half of the respondents stated that divisional goals are not consistent with overall corporate goals. Furthermore, 37.5 percent of the respondents indicated that they do not have any formal procedures to establish if the transfer pricing objectives have been achieved. Only 26.3 percent of respondents indicated that they had formal procedures designed specifically for this purpose. These results lend support to earlier findings that pinpoint to the ad hoc nature of determination of transfer prices.

Although the findings specified in Table 3 do not suggest any particular pattern, the ease of understanding, profit maximisation, enhancing goal congruence and divisional evaluation appear to be the most commonly stated objectives of transfer pricing. It should also be noted that apart from the current research, the results relate to manufacturing organisations.

Table 3

Comparison of transfer pricing objectives reported under selected studies

Rankings are in terms of importance with 1 being most important.

	Current Research	Elliott (1998)	Mueller et al. (1997)	Alam and Hoque (1995)	Grabski (1985)	Benke and Edwards (1980)	Tang (1979)	Fremgen (1970)
Ease of understanding	1	2		2		3		

Optimal pricing	2							
Enhancing goal congruence	3		3		2	1		
Divisional evaluation	4		2	1		2	2	2
Managerial motivation								4
Preserving divisional autonomy					1			
Communicating information that results in desirable decision making by managers			1					
Profit maximization		1					1	1
Evaluation of divisional manager's performance				3				3

Transfer pricing methods used and multiplicity of methods. Overall predominance of the cost-based transfer pricing method is evident over the years and across different countries (Table 5). This finding is consistent with Zeithaml *et al.* (1985) who found that service firms prefer cost-orientated pricing and Mills and Sweeting (1988) who also reported that most service firms (68%) chose cost-based pricing methods. Drury and Tayles (1995) argue that "conventional wisdom rejects the use of full costs".

The cost-based transfer pricing does not reflect customer perceived value as there is hardly any incentive for unit managers to be concerned about providing value to internal customers. Despite its major weaknesses why do companies continue to favour cost-based methods warrants further investigation. The current survey also reveals that only 10 percent of respondents stated that they were free to source their requirements from external suppliers where the same are internally available.

Sahay (2003) considers the use of actual cost of production of the transferred good as a natural choice for organizations because it is easy to implement. Actual full costs are calculated by dividing all fixed and variable expenses for a period into the number of units produced, Use of actual full costs also allows the supplying division to recover its costs without too much effort and, consequently, there is hardly any incentive left for the supplying division to improve

efficiency and reduce cost levels. Sahay (2003) also claims that a transfer pricing policy based on actual costs is usually easy to implement, and is a natural choice, especially where a market price is not readily available for the intermediate good or service. Sahay's conclusion is based on the premise that a positive mark-up is desirable because it motivates the seller to reduce costs by undertaking specific investments, and the value to the firm from such investments more than offsets the cost of the mark-up in the form of reduced levels of internal transfers.

Butz and Goldstein (1996) report often troubled relationships between internal producers and their customers. Internal providers are often seen as overpriced, unresponsive, producers of shoddy services and goods. Although there is a consensus on how important it is to get the transfer price right (Benke and Edwards, 1980; Eccles, 1985), there is also evidence that, pricing for both external and internal customers lacks rigour and is largely arbitrary (Emmanuel and Mehafdi, 1994).

The Business Manager of a service organisation admitted:

> "To be honest with you, it *(the general pricing policy)* is very unstructured and there really isn't one. So, a little bit haphazard, a little bit slapdash".

The Funds Manager at one of the major banks in Australia made a statement in the same vein:

> "Internal pricing is ad hoc. It's decided on at upper management level, but it is not stringently adhered to".

Multiplicity of transfer pricing methods. The results reveal that the use of more than one transfer price at a time is common with 87.5 percent of respondents (Table 4). Even though the finding supports Tang's (1992) result, it contrasts significantly with the results obtained in Chenhall's (1979) and Tomkins' (1973) surveys. It is not known whether the difference in conflicting survey results is attributable to differing time periods the surveys were conducted or whether there are other contributing factors. The issue may merit an investigation.

Table 4

Single versus multiple transfer price

	Current Research	Tang (1992)	Chenhall (1979)	Tomkins (1973)
Single method	12.5%	8%	89.6 %	73%
Multiple method	87.5%	92%	10.4 %	27%

Most respondents attribute the popularity of using multiple transfer prices to different responsibility centres (55.7%) and different products (31.4%). As indicated in Table 4, the present survey also reveals that the majority of respondents that use more than one transfer pricing basis indicated that the reason behind using multiple transfer prices is involvement of different responsibility centres (53.4%), different products (30.1%) and different locations (8.2%).

Locus of transfer price decisions. Consistent with Arpan (1972) who, in regard to international transfer prices, found that the setting of transfer prices was the absolute prerogative of parent company executives regardless of parent's nationality, the current research indicates that the locus of decision making rests with headquarters. Headquarters solely set transfer prices in 60 percent of cases, and in 27.5 percent of cases transfer prices are set jointly with headquarters and divisional management. This finding stands in contrast to Eccles' (1985) view that in competitive organisations, business units rather than headquarters should determine transfer prices.

How firms decide if transfer pricing objectives have been achieved? Most firms (37.5%) state that they have no formal procedures to establish if the transfer pricing objectives have been achieved. Only 26.2 percent of respondents indicate they had formal procedures designed specifically for this purpose. Almost a quarter of respondents (22.5%) use their intuition to see if the transfer pricing objectives set have been attained. Five percent of respondents do not believe it is important to explore this relationship.

Review of transfer prices. Annual review of transfer prices appears to be the most common practice. Eighty-four percent of respondents review transfer prices annually while 5 percent review semi-annually. The most common circumstance that prompts transfer price change is the strategic nature of internal trade (41.3%) followed by changes in organisational structure (25%).

Table 5

Transfer pricing methods used

	Current Research	Oyelere & Turner (2000)	Alam & Hoque (1995)	Drury et al. (1993)	Tang (1992)	Jaye & Blayney (1991)	Bafcop et al. (1991)	Mehafdi (1990)	Mostafa (1982)	Tang (1981)	Chenhall (1979)	Tang et al. (1979) US firms	Tang *et al.* (1979) Japanese firms	Vancil (1979)	Tomkins (1973)

Other market based					4.0 %						12.3 %	8.2 %	16.0 %		
NEGOTIATED	21.3%	7.14%	11.6 %	20.7 %	16.6 %	11.0%	12.1 %	42.4 %		27.6 %	33.3 %	18.1 %	19.3 %	22.2 %	21.5 %
Other	9.4%			14.3 %	0.5 %	11.0%	9.1 %			7.4 %	9.5 %	1.7 %	1.0 %		4.5 %

Conflict arising from transfer pricing. Crompton (1972) argues that cost-based methods, whether they are full cost or variable cost, are at odds with the goal congruence objective of transfer pricing and as a consequence the use of cost-based transfer pricing methods is apt to give rise to conflict. Spicer (1988) reports that the presence of internal transfer of goods and services is the source of inter-divisional conflict. Consistent with the literature, the current research demonstrates that almost 90 percent of respondents experience some kind of conflict emanating from transfer pricing (Table 6).

Table 6

Types of conflicts arising from transfer pricing

	Division	
	Frequency	Percent
Opportunistic behavior	27	37.5
Negative motivation to reduce costs	18	25.0
Perceptions of hostility between departments	2	2.8
Restricted flow of information	7	9.7
Lack of trust between departments	7	9.7
Dissatisfaction with the company's internal pricing policy	8	11.1
Others	3	4.2
Total	72	100.0
No answer	8	
Total	80	

The most common cause of conflict is opportunistic behaviour (52.2%) and negative motivation to reduce costs (32.8%). Almost half of respondents (49.3%) indicated that they use negotiations between divisions to resolve conflicts and 41.1 per cent stated that top management's forced solution for conflicts is their practice.

The Account Manager of a major telecommunications company stated:

"Yes, we have conflicts (*arising from internal pricing*) all the time. One of the biggest problems we have had here is that they *(internal suppliers)* always overcharge".

The divisional manager at the same telecommunications company who supplies services to internal departments said on pricing strategy he employed:

"I have a cost to recover to a zero budget. We look at total compensation for all my employees including my salary and benefits. We look at training. We look at annual leave. We look at all the travel and living expenses that we incur……I recover that money back into my department every month and I should end up with zero…. I purely need to recover all the money that the company spends on having me here."

Extent of intra-corporate trade. A comparison of prior surveys associated with the extent of internal trade as a proportion of total company sales is shown in Table 7. The present survey's findings are consistent with many prior studies which reported small volumes, typically less than 20%. Although no researcher so far has investigated the reasons for this low level of internal trade, Williamson (1993) argues that a relatively higher proportion of internal trade can be achieved through a higher level of vertical integration.

Internal value creation and setting transfer price. About 35 percent of divisional staff considers value creation for internal customer very important or important in setting transfer prices. For 41.8 percent of respondents, the issue of setting transfer prices with a view to create value for internal customers is either of little importance or unimportant. Internal providers can prosper only when they approach their customers with the desire to provide the same level of increased net value as their external competitors (Butz and Goodstein, 1996).

859

A bank executive interviewed stated:

> "For me the benefits that I receive from most internal service transactions are very little. The majority of the time, the benefits that I receive from the internal service is too little and too late. For example the deliverables are over budget, over time and fail to satisfy quality expectations."

Table 7

Intra-corporate trade (expressed as a percentage of total company sales)

	Current research	Elliott (1998)	Drury et al. (1993)	Mehafdi (1990)	Scapens et al. (1982)	Tang (1981)	Chenhall (1979)	Vancil (1979)	Tomkins (1973)
0-less than 5%			36%						
0-less than 10%		27%		55%		50%			
5-19%			36%						
10-25%		8%		21%					
0-19%	75.0%		72%				52.6 %		% 91.1
0-less than 15%								77.1 %	
15% and above								22.9 %	
20-39%	13.8%								
20-49%			16%						
25% +		13%		24%	15% (UK) 18% (USA)	25%			
40-59%	11.2%								
50% +			13%						

Thirty-five percent of the firms surveyed report that the internal supplier cares about reducing their costs without sacrificing what they from the services. 25 percent are undecided. Smith and Nagle (2002) believe that 'willingness to pay' is important to tactical pricing but it is woefully inadequate as a basis of pricing strategy. Pricing strategists manage demand by making subtle changes to capture different levels of price from different types of buyers, by creating incentives for some customers to change when or how they buy, and by communicating information and framing price offers that cause customers to view the offer more favourably. To support those efforts, pricing strategists need more fundamental

customer information than simple willingness to pay. They must understand the level and antecedents of value especially in the business-to-business (B2B) markets where benefits can be quantified and value can be readily measured. (Smith and Nagle, 2002). If value is of concern, according to Blois (2003), both the buyer and the supplier should seek to enhance the value of their operations. Following Zeithaml (1988), the net value is defined as the sum of perceived benefits less the sum of all the perceived costs. For 60.8 percent of respondents, if and how internal customers value an internal transaction is not considered as an issue. Only 39.2 percent of respondents stated that it is important for them to find out if and how internal customers value the services they acquire internally.

Lack of internal customer orientation is also evident with 30 percent of respondents indicating that there is an association between satisfaction of internal customers and external customers.

The Account Manager of a telecommunications company commented that:

> " …one problem that we have is that they *(internal divisions)* are a little removed from the end customer. The time that they see it is if we then go back and say you are too costly, or if the customer goes back and says you are too costly, then you need to do something".

Given that overhead allocations and transfer pricing decisions are typically made at the headquarters level, and out-sourcing internally-available service is either restricted or totally disallowed, deciding who the internal customer is becomes difficult.

The notion of value appears to be of little concern to divisional managers and this may explain the divisional managers' indifference to value. The ability to meet customer requirements is vital not only between two separate organisations but also within the same organisation (Oakland, 1993).

Table 8

Importance of value creation for internal customer in setting transfer price

	Frequency	Percent
Very important	9	11.4
Important	17	21.5
Undecided	20	25.3
Of little importance	29	36.7
Not important	4	5.1
Total	79	100.0
No answer	1	

The Project Manager at a telecommunications company explained the lack of focus on internal customer value by stating:

> "There are many conflicts due to internal pricing mainly because not all organisations within our company are aligned to deliver value to the customer. This is a direct result of internal service providers having organizational metrics which are in direct conflict with delivering value to the *(external)* customer."

The interplay between transfer price and perceived value. One of the principal objectives of this research was to identify latent variable (s) or factors present in the pattern of correlations among those variables. It is used to study the interrelationships among variables in an effort to find a new set of variables which can express what is common among the original variables (Stewart, 1981). Although data collection tools benefit from the extant literature, as one of the chief aims of the present research was to uncover the underlying factor structure of measures and to examine their internal reliability, no hypotheses were made about the nature of relationships among variables. Exploratory factor analysis was employed to detect factor structures and principal factor analysis was used to extract factors.

Prior to analysis, tests were performed to check if the data were appropriate for factor analysis. These tests include missing data analysis, test of normality using skewness and Kurtosis

statistics, sampling adequacy using the Kasier-Meier-Olkin statistics, anti-image correlation matrix, Bartlett's test of sphericity, presence of substantial correlations, test of linearity, face validity, content validity, construct validity and convergent validity.

The correlation matrix has shown no evidence of multi-colinearity among the variables.

A total of fifty-seven variables were operationalised. Six scales were constructed to evaluate both components of value: benefit components (assurance, responsiveness, reliability, empathy, tangibles, flexibility and innovation) and cost components (price, time/effort and energy and psychic costs). The principal objective of the analysis was to identify latent variable (s) present in the pattern of correlations among those variables.

Using Churchill's (1979) methodology, scales were constructed based on the literature (i.e., Parasuraman *et al*., 1988; Porter, 1985; Brady and Cronin, 2001) and pilot study findings. The reliability of scales is summarised in Table 9. The initial solution provided in Table 10 contains variables which are standardized to have a mean of 0.000 and ± 1.000. Using Kaiser's criterion of 'eigenvalue > 1.000", the initial solution suggests a seven- factors solution. The seven factor solution is also consistent with Gorsuch (1983) who recommends that regardless of the method used to decide how many factors to retain, they should collectively account for at least 70 percent of the total variance. Examination of variances given in Table 10 reveals that the seven components selected for extraction collectively account for 78.102 percent of the total variance.

Table 9

Reliability scores (Cronbach's Alpha) of scales

CONSTRUCT	Number of items	Cronbach's Alpha based on standardised items	Comment	Inter-item correlations (range)
Assurance	4	0.938	Excellent	0.756 - 0.852
Responsiveness	7	0.946	Excellent	0.677 - 0.809
Reliability	5	0.923	Excellent	0.634 - 0.798
Empathy	5	0.791	Very good	0.072 - 0.681
Tangibles	3	0.883	Very good	0.618 - 0.799
Flexibility and innovation	6	0.948	Excellent	0.654 - 0.870
Alternate solutions and	8	0.942	Excellent	0.541 - 0.766

customisation				
Price	8	.844	Very good	0.062 – 0.685
Time, Effort and Energy	3	.882	Very good	-0.055 - 0.789
Psychic costs*	1	-.282	Very low. Inconsistent	
Overall service value	5	0.852	Very good	0.271 - 0.698

*Owing to its low reliability score (α=-.282), the psychic scale was discarded.

Table 10

Initial solution

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings			Rotation Sums of Squared Loadings(a)
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total
1	27.828	57.975	57.975	27.828	57.975	57.975	15.836
2	2.305	4.803	62.777	2.305	4.803	62.777	12.832

10	.718	1.497	83.202				
11	.697	1.452	84.653				

Extraction Method: Principal Component Analysis.

a When components are correlated, sums of squared loadings cannot be added to obtain a total variance.

Factor 1 is predominant with an eigenvalue of 27.828 and accounts for 57.975 percent of the variance. Factors 2-7 have relatively smaller eigenvalues. Factors 8 and above were found to be insignificant as their eigenvalues were less than 1.0, and these factors were dropped. Inter-item correlations were examined and variables with inter-item correlation of less than 0.30 were dropped. Also factors with loading of less than 0.40 and cross loading of less than 0.30 were deleted.

The component matrix obtained shows that each variable's loading was high on one factor (close to 1.000) and low (to close to zero) on other factors. The variables that load on multiple

864

factors complicate both the analysis and interpretation of factor solution. For this reason, the data were rotated using the varimax rotation with Kaiser normalisation.

A close examination of factor loadings given in Table 11 shows that factor 1 had the highest loading on assurance dimension followed by reliability. To obtain a clearer pattern, the data were rotated again using the Direct Oblimin method which shows that assurance loadings were slightly stronger than responsiveness loadings. Assurance encompasses behaviour of employees of the internal supplier that instills confidence in the internal buyer, trustworthiness as well as courtesy, competence, knowledge and skillfulness of the internal supplier.

The responsiveness dimension includes timely communication to the internal buyer when services will be performed, willingness displayed by the employees of internal supplier in responding to requests expediently and efficiently, listening to their problems, providing quick answers and solutions, ability to provide emergency service deliveries and welcoming complaints.

Loadings on reliability and empathy dimensions are relatively lower. Factor one was renamed 'confidence'. Factor 2 was loaded on both "Alternative Solutions and Customisation" and "Flexibility and Innovation". Alternate solutions and customization loadings are relatively stronger than the Flexibility items.

The alternative solutions and customisation was labeled 'solution' and includes the capability to customize the service offering, ability to meet unique specifications, capability of offering a range of services, offering different services from its competitors, willingness to help should problems arise, possession of specialized expertise in the internal buyer's area of activity, comprehensive knowledge about processes of the buyer's business and utilization of new technologies in resolving internal buyer's problems.

7							.454

The Flexibility construct includes ability to identify needs before they are raised, commitment to improvements, willingness to meet needs beyond contract terms, provision of assistance whenever such assistance is needed by the internal buyer. Introduction of breakthrough

solutions and new technologies and commitment to be one step ahead of what the competition offers. The variance explained by each of the remaining factors (3 – 7) ranges between 2.434-3.855 percent.

From the weighting point of view, given their lower eigenvalue scores and the percentage of variance that they explain, these remaining factors appear to be insignificant. Although inspection of Table 11 suggests a seven-factor solution, the most dominant factor among all is factor 1, which on its own, explains 57.975 percent of the variance. There is also a large gap between factor 1 and factor 2. The variance explained by factor 2 stands at mere 4.803 percent of the total variance.

The factor analysis reveals that the dominant factor in intra-divisional exchange of services is the responsiveness of the internal division, and domestic transfer price does not seem to play a significant part in internal transactions. The overall findings offer empirical support for the notion that although price is regarded as a component of sacrifice (Brady and Cronin, 2001) it does not correlate strongly with the dimensions of benefit and sacrifice. This result is consistent with the findings of Frost and Kumar (2000) who conducted a survey on Singapore Airlines to determine the dimensions of service quality among internal customers. They found that responsiveness was the most important dimension for internal customers. The results of this research are also consistent with Cronin *et al*. (2000) who found that service customers (in an external customer context) place greater importance on the quality of a service than they do on the costs associated with its acquisition. Stafford *et al*. (1998) examine service quality and customer service satisfaction in the automotive insurance business using SERVQUAL (where price was not used as a variable) and find that reliability is the most important dimension.

4. Conclusion

This paper reports the results of a survey of transfer pricing practices in Australian service organizations and whether transfer price is associated with the internal customer's perception of value derived from intra-organisational exchange of services. The present research demonstrates that there are similarities in transfer pricing practices in both manufacturing and service organisations. Although cost-based pricing strategy is often responsible for arbitrary charges, it still appears to be the most favoured method in both manufacturing and service businesses.

Headquarters' heavy involvement in setting transfer prices may be seen as an indication that internal departments do not operate under competitive market conditions. This view is also supported by the finding that most internal departments face restrictions in out-sourcing. Lack of internal customer orientation is also evident. Only 30 percent of respondents believe there is an association between satisfaction of internal customers and external customers. Only 35 percent of divisional staff deem value creation for internal customer is important in setting transfer prices while 41.8 percent regard taking into consideration the value creation in pricing services for the buyer as either "unimportant" or "of little importance".

External customers get precedence over internal customers. Perceptions about internal customer orientation may change when a positive relationship can be established between internally created value and either net operating profit or shareholder value. The research also highlighted that among all value dimensions, internal buyers responsiveness was used as a key criterion in assessing the value of an internal service delivery. The two most significant contributions of the current research lie in the incorporation of transfer price as a sacrifice variable for the internal buyer and in providing insight into the nature of transfer pricing in non-manufacturing settings.

5. Limitations

It is important to note the limitations associated with this study. First, as reported by Slater and Narver (1998), and Parasuraman (1997), the criteria customers employ for assessing value may change over time. Therefore, results reported in this paper reflect responses of managers at the time of research. Second, data analysis has been based responses from single respondents within each subject organisation. Absence of responses from multiple respondents from each organisation should be considered a limitation. Third, the present research is exploratory and aims to gain a broad understanding of transfer pricing behaviour and practices of service organizations in Australia and is carried out on a sample from selected industries. Therefore, generalization of findings was not intended to be made. Finally, inherent limitations of mail surveys (i.e., giving convenient answers, misinterpretation of questions, knowledge of respondent, whether questions have been answered conscientiously and truthfully, motivation, etc.) apply.

6. Implications for further research

There are several implications for future research. One area that warrants further research is why companies continue using cost-based transfer pricing despite its well documented weaknesses. Future empirical research should focus on reasons underlying the transfer pricing method choice preferably using case study or Interviewing. Another suggestion for new research is to explore both transfer pricing practices and the development of internal customer value in manufacturing organisations and compare findings with that of non-manufacturing organisations.

Following Brown *et al*. (1993), who doubt whether a scale to gauge service quality can be universally applicable across industries and heterogeneity of services, consideration may be given to develop an industry-based scale to measure value. Finally there is another direction for new research which involves investigation of the relationship between internally produced value and net profit and / or shareholder value. Lack of a theory is an impediment to

comprehensive understanding of transfer pricing. It is certainly a challenge. To this end, analysis of case studies using a grounded theory approach would be recommended.

CEO COMPENSATION AND FIRM PERFORMANCE: AN AUSTRALIAN PERSPECTIVE

Siti Seri Delima Abdul Malak, University of Adelaide
Kate Harris, University of Adelaide

Abstract

The international literature on executive pay and performance has addressed the association between various components of executive pay and firm performance against the backdrop of agency theory. Australian research is limited and the mixed results have been attributed to the lack of disclosure, particularly in regard to equity based compensation. This study addresses this deficiency by examining the relationship between the components of CEO compensation, namely fixed salary, cash bonuses, equity based remuneration and other benefits, and firm performance using a sample of 80 Australian firms over the period 2003 to 2006, a period which spans disclosure reform in Australia. The effect on CEO compensation of corporate governance variables, ownership structure, CEO tenure, risk and size are controlled. The results are consistent with the proposition that performance based compensation (cash bonuses and equity based remuneration) are effective in aligning the interests of the CEO to that of the shareholders, with positive associations between these components of CEO compensation and firm performance. Greater numbers of independent directors on the board of directors are associated with greater performance based compensation, suggesting that corporate governance measures are effective in mitigating agency problems. CEOs with firm ownership and with longer tenure are less likely to have equity based compensation. Longer serving CEOs are likely to have accumulated share ownership over their tenure, and are less likely to

need additional incentives to act in shareholders' interest. Overall, the study provides evidence that CEO pay structure is an effective tool in resolving agency problems between the CEO and shareholders, and refutes the public criticism levelled at high CEO remuneration.

Introduction

The generous level of Australian CEO pay has been subject to much public criticism. CEO compensation is consistently in the news, and was particularly evident following several large corporate collapses in Australia in 2001[1], and more recently during the global financial crisis. Even Prime Ministers have criticised the excessive level of pay awarded to Australian CEO's[2].

The separation of ownership and management in a company, suggests a moral hazard problem (Jensen and Murphy, 1976). Because of this, incentives need to be offered to the CEO in order that they align their interests with those of the shareholders of the company. Typically, the shareholder goal is to maximise the value of the company, and to induce the CEO to achieve this, CEO compensation has been used as incentive. Incentives such as bonuses based on annual profit, share grants, grants of options over shares of the firm have been included in executive remuneration packages. If CEO compensation is based on current and future performance of the firm, then one would expect to find a close relationship between these components of the remuneration package and the return to shareholders. The sensitivity of CEO remuneration to firm performance has been extensively investigated (for example Murphy, 1999). Results from international research is largely

---

[1] For example HIH and OneTel
[2] Former Prime Minister John Howard criticized, in 2007, the amount received by the CEO of Macquarie Bank and Telstra. More recently, Prime Minister Kevin Rudd condemned the excessive salary packages, even at most recent the G20 summit.

consistent with the agency proposition that Ceo remuneration is positively associated with firm performance. Earlier Australian research on pay-performance sensitivity had mixed results (for example Craswell, Taylor and Saywell, 1997), but more recent studies have found a positive relationship between executive pay and performance (Matolcsy, 2000, Clarkson, Nichols and Walker, 2005, Merhebi, Pattenden, Swan and Zhou, 2006). Not all of these studies included all components of CEO pay, some predated the introduction of more performance based incentives in executive pay in Australia and also did not include firm years since the introduction of more extensive disclosure requirements on executive remuneration.

This study investigates the pay performance relationship of 80 Australian firms in the period from 2003 to 2006, using total CEO remuneration as well as the individual components of CEO remuneration. The period of study spans the introduction of international accounting standards in Australia as well as more enhanced remuneration disclosures. It also precedes the global financial crisis, which has seen the eroding of shareholder returns. Although the study spans regulatory changes, a significant year affect was not found. A positive association was found between changes and CEO total pay and performance for the current period. This was largely due to the effect of the share-based component of remuneration. There was also a positive association between the cash bonus component of remuneration and accounting performance. These results indicate the effectiveness of tying executive remuneration to firm performance. No significant association between the salary and other benefit components of CEO remuneration and shareholder return was found.

The next section discusses the prior research that has attempted to establish a link between executive compensation and performance of the firm. It also reviews other factors that may impact on the level of executive compensation. This is followed by sections that develop the hypotheses, research design and a discussion of the results of the hypothesis testing, and finally a conclusion.

Prior research

With the problem of moral hazard, a constant or fixed salary would not entice executives to take any more additional effort that would increase the shareholders wealth (Holstrom, 1979). Another potential problem is that executives may undertake bad decisions that would affect the wealth of the shareholders through the reduction in accounting profit or the market value of shares, but the executives would not be penalised by a reduction in pay since their salary is fixed (Fama and Jensen, 1983). A similar argument could be applied to other benefits such as termination benefits, housing allowances, car allowance and additional perquisites attached to the employment contract. Employment contracts that incorporate performance hurdle incentives for executives have been used in attempts to align the interests of managers and shareholders. Other mechanisms, both internal and external, may work in tandem with contracts in disciplining executive's behaviour. Strong corporate governance, for example independent directors on the board, the managerial labour market and the market for takeovers could mitigate the moral hazard problem.

Executive remuneration contracts could include rewards in the form of a bonus for achieving a certain performance threshold. This performance

threshold is usually some accounting measure of profit (Watts and Zimmerman, 1986, p 208). There is, however, an inherent weakness of an annual bonus as a component of executive pay. Earnings are open to manipulation through a degree of discretion in accounting choice exercised by executives (for example Healy 1985). Executives whose performance is based on accounting numbers are assumed to be detached from the effect of their decisions on the shares price of the firms. Shareholders on the other hand would want to maximise their capital gain from movement in share price. Concerns with manipulation of accounting numbers by management have been argued to be the catalyst for shift to more equity based compensation. Unlike a bonus, which is usually based on accounting numbers, equity based compensation incorporates 'public information' (share price) which cannot be easily manipulated by the executives to increase their level of compensation (Hall and Murphy, 2003). By providing the executives incentives in the form of share ownership, executives share the perspective of the principal - to improve the market performance of the firms (Cohen, Hall and Viceira, 2000). Share based remuneration could include options or restricted shares.

Hall and Murphy (2003) argue that options would increase the retention rate of the executives. The maturity of the options is usually long term thus the executives cannot exercise the options and make any gain in the short term. For the executives to enjoy any gain, they would have to remain in the firm until the options mature. They also argue that a further benefit with issuing options is that firms appear not to have incurred any cash outlay in attracting employees. In effect, firms are borrowing from their executives for their

current employment services and in return the employee receives the possible future payoff from the options.

Firms have issued restricted shares to the executives where the shares would be vested once the firms achieve certain long-term performance thresholds. For instance the Investment and Financial Services Association (IFSA) recommends that the performance thresholds should offer executives the incentive to significantly improve upon medium and short term performance of the firm and shareholder return[3]. The most common thresholds in Australia ASX 200 firms are a measure of total shareholder return.[4] The survey by Equity Strategies on Australian executive plans in ASX 200 firms in 2003 found that 49% of the firms used total shareholder return as their primary performance threshold (cited in Stapledon, 2004).

The corporate collapse of Enron and WorldCom in Unites States attracted a lot of public and political scrutiny of executive compensation (Stapledon, 2004; Hill, 2004; Huang, 2006, Hill 2006). The corporate collapse of OneTel and HIH in Australia, which ran parallel to Enron (Hill, 2004) had a similar impact.

For an optimal compensation contract to be achieved it should be tied to a firm's performance. A pay performance model measures the sensitivity of the changes in executives' compensation for given changes in a firm's value. Murphy (1985) termed this pay performance sensitivity. Jensen and Murphy (1990) found a positive association between pay and performance. The change in performance included both current change and a lagged change. Murphy (1999) updated these estimates and found an increase in sensitivity

---

[3] IFSA, Executive share and options Scheme Guidelines (IFSA, Sydney, 2004) para 7.1
[4] changes in firms' share and dividends paid.

of pay to performance. This coincided with the increase in share options in executive compensation packages in the 1990s in United States.

Australian research on pay performance is limited. The majority of studies found either an insignificant or no association between executive pay and performance (Defina, Harris and Ramsay, 1994; Izan, Sidhu and Taylor, 1998; O'Neill and Iob, 1999; Fleming and Stellios, 2002; Coulton and Taylor, 2002). Craswell et al (1997) found mixed results and Matolcsy (2000), who reviewed pay performance sensitivity in periods of economic recessions and booms, found a positive association between executive pay and performance. Stapledon (2004) attributed the lack of association between pay and performance in Australia to the time period of the studies. He argued that the data used by the studies pre-date the introduction of more performance based compensation into Australian executive pay[5].

More recent research on Australian pay performance sensitivity has found a positive association. This is more consistent with overseas findings. Clarkson et al. (2005) found that the salary and bonus component has a positive association with performance. In addition they furthered the empirical research on Australian CEO's pay by measuring the sensitivity of options to performance, but their result is inconsistent with the prediction of agency theory. They failed to find a significant association between options payment and performance. They argued that this anomaly resulted from the lack of disclosure for options compensation in the annual report prior to the tightening of remuneration disclosure in Australia. Merhebi, et al (2006) also found a significant positive association between pay and performance. However, their

---

[5] For instance, the Australian Council of Superannuation Investors showed that fixed salary was reduced from 90.5% from 1987 to 42.8% in 2002, followed by an increase in performance based incentives from 9.5% to 57.2% (cited in Stapledon, 2004, p13).

result may not reflect the real association between pay and performance since their model did not include equity holdings in measures of CEO pay and so did not address the anomaly in the findings by Clarkson et al (2005).

Factors other than performance can also impact on the level of CEO pay. A positive association between compensation level and size has been well documented (for example Murphy, 1985; Gomez-Mijia, Tosi and Hinkin, 1987; Jensen and Murphy, 1990; Smith and Watts, 1992; Hall and Liebman, 1998, Core and Guay, 2002). In addition, the pay-performance sensitivities of larger firms were found to be lower (Core and Guay, 2002).

Risk is another factor that can affect pay-performance sensitivity. However, by inducing executives to take on more risks through option holdings, the principals would need to consider the optimal point where the marginal cost from excessive risk would harm the companies. Holstrom and Molgrom (1987) predicted a negative association between pay and firm risk. This negative association was confirmed by Argawal and Samwick (1999), but Core and Guay (2002) found a positive association after controlling for form size. Bothe these studies used the variance of the return on firm's shares as a proxy for risk. Using leverage as a measure of risk, Lyengar, Williams and Zampelli (2005) found that pay performance sensitivity decreases (increases) as leverage increase (decreases).

Executive experience could affect the level of CEO pay: executives with more experience would expect higher compensation. In an Australian study, Clarkson et al (2005) included age and tenure as a proxy for experience. They found an insignificant association between age and tenure on the level of CEO compensation. Brunello, Graziano and Parigi (2001) included

executive's experience in their study of the pay performance sensitivity of Italian firms and found a positive, but not significant association between executives' experience and executive pay.

Core, Holthausen and Larcker (1999) argued that stronger corporate governance characteristics in a firm are associated with lower level of total CEO compensation and higher incentive based payment. The board composition, if made of a majority of independent directors, would control the rights to evaluate management decisions and this is argued to mitigate decisions that are against the principals' interest. In the case of compensation, this could prevent excess executive pay that is not linked to the firm's performance.

Lawrence and Stapledon (1999) in an Australian study, found no association between the proportion of independent directors on the board and the level or nature of CEO compensation. They argued that the period of their study pre-dated the Australian public interest in corporate governance and that the independent directors may not have been performing effectively.

The level of CEO ownership could also influence the pay performance sensitivity. From an agency theory perspective, executives who have more ownership would have lower pay since they do not need additional incentives to align their goal with the shareholders (Jensen, Murphy and Wruck, 2004). Clarkson et al (2005) found a significant negative association between Australian CEO firm's ownership with their level of pay, consistent with the above proposition.

A firm's ownership structure has been argued to have an association with the level of pay and performance. A firm in which independent[6] individuals or groups hold more than 5% of share ownership is an owner controlled firm. While a firm which has no independent party holding more than 5% of shares is deemed to be a management controlled firm. Dyer, Schwab and Theriault (1976) found executives in management controlled firms do not base their pay on performance. An owner controlled firm would, however, rely on performance as a basis of executives' pay since it is a proxy for the managerial effort. Gomez-Mejia et al (1987) found that a management controlled firm has a low pay to performance sensitivity and the reverse is true for owner controlled firms. Similar results were also found by Ke, Petroni and Safieddine (1999) and Blair and Kaiserman (1983).

The quality of audit is also argued to influence the level of excess pay (Clarkson et al, 2005). Firms which are audited by higher quality auditors, represented by the 'big four' accounting firms are argued to have lower level of excess pay. A high quality audit should detect any earnings management by the CEO in order to maximise their annual cash bonus. For instance, Becker, Defond, Jiambalvo and Subramanyam (1998) found that the level of earnings management is lower in firms that are audited by 'big-four' accounting firms. However, Clarkson et al (2005) failed to find a significant association between the level of pay with the quality of audit.

Hypothesis development

---

[6] Is not involved in the actual management of the companies or is on the board

Because it is impossible to achieve perfect monitoring by shareholders of management behaviour (Easterbrook 1984, Fama and Jensen 1983), it has been argued that the best proxy for direct monitoring is the performance of the firm (Clarkson et al 2005). By linking executive compensation to the performance of the firm, executives have incentives not to engage in behaviours that reduce firm value (Tosi and Gomez-Mejia 1989). If they are penalised with lower remuneration for firm non-performance, then they are motivated to maximise their effort to increase the value of the firm. Lambert (1983) argued that the optimal executive contract should incorporate both the current and long-term performance of firms. Options and shares granted to executives are usually based on long-term performance hurdles (Stapledon 2004) and executive pay has increasingly incorporated both bonuses (based on current profitability) and share-based remuneration (see Jarque, 2008, p.269 for an indicative table) into the remuneration package. Total CEO compensation can be based on both current and prior periods (Merhebi et al, 2006). Prior studies have shown that only one lagged measure is necessary. Any additional lag was found to be insignificant (Murphy, 1999 and Jensen and Murphy, 1990). Thus if CEO compensation is structured to align executive and shareholder interests, then a positive association between shareholder return and executive compensation would be expected:

Hypothesis 1: *Changes in the level of total CEO compensation from one period to another would be positively associated with changes in firm performance over the same and the prior period.*

Consistent with earlier studies in Australia (for example Coulton and Taylor 2002, Clarkson et al 2005, and Rankin 2006), the components of executive

886

remuneration will also be examined to determine if there is any relationship between these components and shareholder return. The components are fixed salary, other benefits, cash bonus and equity based pay. Salary is fixed at the beginning of a period, so would not vary with changes in firms' performance in the current period. Similarly, it is difficult to tie other benefits to a firm's performance as such benefits included perquisites like superannuation, car and housing allowances (Stapledon 2004). Thus it is difficult to predict the relationship between changes in base salary and changes in other benefits with changes in firm performance.

Hypothesis 2: *Changes in the level of CEO fixed salary from one period to the next has no association with changes in shareholder wealth over the same period.*

Hypothesis 3: *Changes in the level of total CEO other benefits from one period to the next has no association with changes in shareholder wealth over the same period.*

The other components of executive pay – namely annual cash bonus and equity based pay – are both incentives offered to executives to ensure they align their interests with that of the shareholders. Cash bonuses are usually based on accounting profit, a short term measure of performance (Watts and Zimmerman 1986). The weakness of an annual cash bonus based on accounting performance measure is that it is open to earnings management by the executives. This has been argued to be the catalyst for the introduction of an equity based pay component into executives' compensation (Hall and Murphy, 2003). A portion of the executives' pay can now be linked directly to the share price of the firms through equity based compensation (Hall and

Liebman, 1998), and executives would no longer be detached from the effect of their business decisions on the share price of the firm. Equity based pay is often tied to the long term performance of the firms so as to also link executive compensation to the long term effect of management decisions (Jensen and Meckling, 1976). The long term performance hurdle of the firm is often based on prior year performance (Stapledon, 2004). Murphy (1999) and Jensen and Murphy (1990) have shown that only the prior year is significantly associated with executive remuneration. The two final hypotheses are thus:

Hypothesis 4: *Changes in the level of CEO cash bonus from one period to another would have a positive association with changes in firms' accounting performance over the same period.*

Hypothesis 5: *Changes in the level of CEO equity based pay (inclusive of shares, performance rights and options) from one period to another would have a positive association with changes in shareholder wealth over the same and prior periods.*

Research design

Sample and data

This study focuses specifically on Australian chief executive officers compensation and its association with firms' performance. Firms are required under s300A(C) of CLRA98 to disclose remuneration details of the five top paid officers of the firm and this will usually include the CEO. Some firms, however, argued that option plans were too complicated to value (Clarkson, Van Bueren and Walker, 2006). The Australian Investment and Securities Commission (ASIC) issued PN68 in November 1998 to address this issue stating that firms should use Exposure Draft ED 2 Share based payment as the basis for valuation, but disclosure remained limited. With the adoption in Australia of international accounting standards in 2005, the requirement for

disclosure and valuing became mandatory. This study spans this period. In addition, Clarkson et al (2005) argued that shareholders would be able to relate more with pay performance figures of the CEO since the role and responsibility of a CEO is well defined within a firm.

The sample firms are a selection of firms that are publicly listed in the Australian Stock Exchanges (ASX). The sampling period is the four years from 2003 to 2006. This addresses the limitation of previous Australian studies that did not include data subsequent to the regulatory changes for executive compensation disclosures.

The sample excludes firms where the CEO was terminated, quit or retired in any of the sampling years and firms where the CEO was appointed midway through the fiscal year. Firms that were publicly listed partway through the start of a sampling year were excluded as were firms that were delisted during the same period. The banking sector was also excluded.

An initial sample of 300 firms was obtained from ASX top 300 companies list for 2007. After excluding the firms that did not meet the selection criteria, 80 firms were included in the final sample.

Firm data, including accounting, compensation and governance data, was collected from the firm's annual reports in the Connect4[7] database. Any missing annual reports were obtained from individual firms' websites. The share price data was compiled from Standard & Poor's website. It is collected for the beginning and ending of each sampled firm's fiscal year for the period of 2003 to 2006.

---

[7] Connect 4 database is an online database that compile extensive records for Australian firms and contained the top 300 firms marked by market capitalisation.

Experimental design

The model used to test the hypotheses is as follows:

$$\Delta \text{(CEO pay)}_{i,t} = \alpha + \beta_1 \Delta\text{(Firm performance)}_{i,t} + \beta_2\Delta\text{(Firm performance)}_{i,t-1} + \sum\delta c \text{ Control}_{t,c} + \varepsilon_{it}$$

Where $\Delta\text{(CEO pay)}_{it}$ is the change in CEO pay for firm i from one period (t-1) to the next (t), $\Delta\text{(Firm performance)}_{it}$ is the change in the performance of firm i from one period (t-1) to the next (t) and $\Delta\text{(Firm performance)}_{it-1}$ is the change in the performance of firm i from the period t-2 to t-1. Control_{it} are the control variables for firm i in period t. The coefficients, β_1 and β_2 are the pay performance sensitivities which are defined as the changes in the CEO compensation for a given change in firms' performance (Murphy, 1985).

$\Delta\text{(CEO pay)}$ is measured as:

$$\Delta \text{CEO Pay} = \frac{\text{Compensation for current year} - \text{Compensation for prior year}}{\text{Compensation for prior year}}$$

Total CEO compensation can be separated into its individual components including fixed cash (base) salary, annual cash bonus, total equity based pay and total other benefits. The equity based pay includes payment of shares, performance rights and options grants. Consistent with previous studies, the options and performance rights value is taken from the annual reports rather than manually calculated using option pricing models Rankin (2006). Other benefits include superannuation, long leave entitlements, car and housing allowances, health care benefits, loans and other miscellaneous benefits.

Total Shareholder Return (TSR) is adopted as the primary measure of a firm's performance. TSR incorporates the capital gain from changes in the share price and dividends from the share of the firm's profit. This follows the original pay and performance model used by Murphy (1985). He argued that since the

majority of the principals of a firm are shareholders, TSR would be the most appropriate measure of performance .In addition, Stapledon (2004) found that the most common performance hurdles in the Australia ASX 200 firms is TSR. As a robustness check, the hypothesis testing would also use Return on Equity (ROE) or Return on Assets (ROA) as proxy for firm's performance. However, ROA is adopted as the main measure of firm performance rather than TSR in the analysis of the relationship between annual cash bonus and firm performance as cash bonuses are usually based on accounting profit rather than a market based measure (Watts and Zimmerman, 1986)

The control variables included are those factors that could influence the level of CEO compensation. These include the proportion of independent directors on the board (Lawrence and Stapledon, 1999), the extent of CEO ownership of the firm (Jensen et al, 2004), the firm's ownership structure (for example Ke et al, 1999), the experience of the CEO (Mcknight and Tomkins, 2004), the quality of the audit (Clarkson et al, 2005), the size of the firm (for example Core and Guay, 2002) and risk (Lyengar et al, 2005).

If there is a majority of independent directors on the board of directors, they would likely limit the level of pay of executives that is not linked to performance (Clarkson et al 2005), so a negative association between the level of independent directors on the board and changes in fixed salary and total other benefits is expected and a positive association with changes in cash bonus and share based remuneration. Substantial independent block holders (those who own more than 5% of ordinary shares) are also argues to limit the level of CEO pay that is not linked with performance.

A CEO who holds significant shares in the firm would not need the additional incentive to align his/her interest since he/she is also a shareholder (Jensen et al 2004). However, the CEO could influence the level of CEO fixed salary and other benefits compensation. A negative association is expected between CEO ownership and changes in total CEO pay, annual bonus and total equity based pay and a positive association with changes in fixed salary and total other benefits. In addition, is expected that CEO with more experience would be paid more.

Larger firms are argued to be able to employ and retain highly skilled executives with higher pay. Up to an optimal level of risk, there should be a positive association between executive pay and performance. Firms that were audited by the Big Four auditing firms are argued to have lower level of excess CEO pay since their audits are of better quality. Measurement of the independent and control variables is summarised in Table 1.

In determining the proportion of independent directors on the board, the definition of an independent director provided in ASX 'Principles of Corporate Governance and Best Practice Recommendations' is used. In measuring ownership structure, substantial block holders are defined by Corporation Acts Section 9 as a person or party that owns more than 5% of the total voting interest in a firm. Independent block holders are defined as shareholders that are unaffiliated with the firms (Clarkson et al, 2005). Firms with no independent party holding more than 5% of shares is deemed to be a management controlled firm. Traditionally both age and tenure have been used as a proxy for experience, however, only CEO tenure is used as a proxy for experience as a significant proportion of the sample firms do not disclose

CEO age in the annual reports. Size is measured as the natural logarithm of total assets and risk is measured using leverage Lyengar et al, 2005). Audit by one of the 'big four' accounting firms is used as a proxy for audit quality.

Table 1: Measurement of Independent and Control variables

Explanatory variables	Denoted by	Measured as
Firm's performance	TSR	Total shareholder return = ((Ending share price + Dividend) – Beginning share price) / Beginning share price
	ROE	Return on Equity = Net profit/Average equity
	ROA	Return on Assets = Net profit/Average assets
Board composition	IND_DIR	The percentage of the board that is independent. The definition of an independent director is stated in the ASX Guidelines
CEO Ownership	CEO_OWN	The percentage of CEO ordinary shareholding over total ordinary shares.
Independence Shareholders (Block)	IND_BLK	The percentage of ordinary shares held by shareholders who held more than 5% of ordinary shares.
Leverage	D_E	Total liabilities divided by total equity obtained from firm's annual reports
Experience	CEO_TEN	The period that the CEO has served in the position during the sampling period.
Size (total assets)	ASSET	The natural logarithm of total assets in dollar value given in the firm annual reports
Quality of Audit	Big_4	Dummy variable where firms that have their annual reports audited by BIG 4 firms are given value of one and zero otherwise.

Data analysis

The dataset is in the form of panel data in which there are observations of the same 80 sampled firms (cross sectional units) over a period of four years (2003 to 2006). Using panel data allows for both cross sectional and time

series effect in the analysis. The dataset was analysed using E-Views Version 5.1.

Panel Generalised Least Squares (GLS) regression was used to test the hypotheses. In order to make valid statistical inferences, several assumptions need to be met (Gujarati,1995). Tests on the data indicate there are probable violations of the heteroskedasticity and serial correlation assumptions. Panel GLS corrects for both cross sectional heteroskedasticity and serial correlation[8].ensuring that the estimates are best linear unbiased estimators. In addition, the large sample size (n=80) should mitigate any normality problems with the data as the Central Limit Theorem predicts that for larger sample sizes (n>30) the distribution of the sample would approach normal (Gujarati, 1995, p.103.). Additional assumptions need to be made with panel data, as one individual year may be different from other years, and individual firm characteristics may not be captured in the existing independent variables. These unobserved effects would be captured by the error term. If the unobserved effects are correlated with the any of the independent variables, the estimates given from the regression could be biased and inconsistent since the error term is now also correlated with the independent variables (Gujarati, 1995). Consistent with Core et al (1999) the study assumes that the coefficients and intercepts of the firms are constant across time. Nonetheless, to test the validity of this assumption the models are estimated in E Views using fixed effects. The fixed effects estimates include all dummy variables for each firm and year. The redundant fixed effects likelihood ratio indicates that

---

[8] GLS incorporates the nature of heteroskedasticity and autocorrelation in the estimation by tramsforming the variables with each firm weight. Ordinary Least Squares (OLS) does not do this. If there is no heteroskedasticity or autocorrelation, the estimates given by OLS and GLS should be the same (Gujarati, 1995)

fixed effects[9] are not necessary to include in the models i.e. the models should not incorporate all dummy variables for each firm and year. However, there are several firms that show significant association with changes in the individual component and total CEO pay. The coefficients for these dummy variables are statistically significant. Often, these firms are the outliers were included in the final regression models. In effect, this is partially controlling for firms that show significant heterogeneity and it also avoids omitted variable bias. However, no year dummies appear to be significant and are not included in the study models.

Results and discussion

Descriptive statistics

Table 2 shows the large range for all components of CEO compensation. Additional analysis of the yearly trends indicates that all components of compensation have increased progressively over the sample period.

Table 2: Descriptive Statistics for Measures of Pay ($AUD)

Variable	Mean	Median	Max	Min.	Std. Dev.
T_PAY	1520617	1064189	6597060	135416	1369580
FIXED SALARY	681185	524062	2298864	12000	467614
BONUS	374215	157520	2720000	-19000	538414
T_EQUITY**	316676	88215	4120209	0	535572
T_OTHER**	280978	96972	4113546	0	500106

** T_EQUITY includes options, performance rights and shares
** T_OTHER includes other benefits and post employment benefits

An analysis of the individual components of executive pay as a proportion of the total pay showed that there was a relative fall in the level of other benefits and fixed pay components, but these falls were cushioned by the increase in

---

[9] By including fixed effects, E Views would include dummy variables for each firms and each year. It could be manually done by including dummy variables for each firms and year in ordinary regression as to see their significance. By doing it manually, we could select which companies that show significant homogeneity to be included in the final model.

bonus pay. Total equity-based pay was a consistent percentage of total pay over the sample period.

Table 3 shows the descriptive statistics for the performance variables and the control variables. A large range of values across the sample firms is evident. The statistics for individual sample years, shows average total shareholder return (TSR) fluctuating from year to year, being the highest in 2003 and 2006. The average accounting based measures, return on equity (ROE) and return on assets (ROA) appeared to be more stable throughout the period. For the control variables there was a large range across all variables which reflects the diversity of firms listed on such a comparatively small stock exchange as the Australian Stock Exchange. 65 firms are audited by Big 4 auditors over all years.

Table 3: Descriptive Statistics for Measures of Performance and Control Variables

Performance Variable	Mean	Median	Max	Min.	Std. Dev.
TSR	56.76%	30.28%	1784.48%	-95.64%	155.03%
ROE	13.52%	13.13%	218.57%	-181.93%	31.46%

Multivariate analysis

A summary of the panel GLS regression results are in Table 4.

The first hypothesis examines the association between changes in total CEO pay and change firm's performance over the same and prior period. The results show that the current year change in total shareholder return is positive and significantly associated with changes in CEO total pay. However, there is a negative and significant association between changes in shareholder return for the prior period with a higher coefficient than the coefficient for change in the current year. This means that total CEO pay is more sensitive to changes in firms' performance for the current year rather previous year. The result is inconsistent with Merhebi et al (2006) who found that Australian CEO total pay was more sensitive to changes in firms' performance for the prior year rather than the current year. Using ROE and ROA as the measures of firms' performance produced a similar finding.

The second hypothesis predicted no association between changes in CEO fixed salary with changes in firm's performance over the same period. No significant association was found for all measures of firm performance. This is consistent with the argument that fixed salary is not an effective incentive in mitigating agency problems. As proposed by Holstrom (1979), fixed salary does not entice the CEO to maximize shareholders' wealth since it is constant, often set at the start of employment contract and does not vary with performance of firms.

Table 4 Regression results for CEO Compensation and Firm Performance

Performance variables	Total CEO compensation	Fixed salary	Other benefits	Cash Bonus	Share-based compensation

It is expected that there should not be any association between changes in CEO total other benefits with changes in firm's performance. Total other benefits include perquisites that often cannot be linked directly to performance or mandatory benefits such as superannuation (Stapledon, 2004). The results support this contention for the measure of shareholders return, but the accounting performance measure, change in ROA is shown to have a positive significant association with change in CEO total other benefits. It could be

argued that the CEO that demonstrates a strong accounting profit performance can demand more additional perquisites.

Hypothesis four predicts a positive association between changes in CEO annual cash bonus for the current period with corresponding changes in firms' performance. It does not include lagged performance for the prior period since annual cash bonus is usually based on short term performance measure rather than long term (Clarkson et al, 2005). Consistent with Core et al (1999) the study adopts changes in Return on Assets (ROA) as primary measure of firms' performance since annual cash bonus is normally based on accounting measure rather than market based measure. The hypothesis is supported and is consistent with Clarkson et al (2005) and Rankin (2006). Similar results were found using ROE as the measure of performance.

The final hypothesis tests the prediction that current change in the level of CEO total equity based pay (inclusive of shares, options and performance rights) is positively associated with change in total shareholder return for the current and the prior period. The change in total equity based pay is positive and significantly associated with a change in total shareholder return for the current period. However, it is negative and significantly associated with a change in TSR for the prior period. This result has two possible explanations. Firstly, as the yearly average of shareholders return indicated, there was a substantial fluctuation from year to year. If equity-based compensation is increasing and shareholder return decreasing from an earlier period, then such a result could be expected despite fixed effects indicating there is no significant year effect. Secondly, if increased equity-based compensation is used to induce the CEO to undertake riskier investments as a result of lack-

lustre performance in the previous period in order to provide a higher return to shareholders in the future, then the positive association between the two variables for the current period indicates the effectiveness of equity-based pay as a means of aligning manager and shareholder interests.

In addition, it is expected that changes in shareholder's return are more sensitive to changes in total equity based pay rather than to changes in other components of CEO pay. Equity based pay is usually granted based on market performance hurdles, often total shareholder return (Stapledon, 2004). Thus, it is argued that the coefficient of association between change in TSR and change in total equity-based pay are larger than that for the other components of pay. Testing supported this assertion.

Similar findings were found using ROE as the measure of firms' performance.

In addition to testing the hypotheses, several control variables were included in the analysis because of their argued effect on the components of CEO compensation. If a CEO has ownership in the firm, then it might be expected that they would require less incentives to align their interests with those of other shareholders (Jensen et al, 2004), and so may have lower pay. The results generally support this proposition. CEO tenure is also argued to impact on the relationship between pay and performance. McKnight and Tomkins (2004) argue that the longer the CEO is in the firm, the more likely they are to receive higher compensation. The results show support for this for total pay and fixed salary, but there is a significant negative association between CEO tenure and changes in cash bonus, equity-based compensation and other benefits. One explanation is that over their tenure, the CEO has

accumulated substantial share ownership, and so does not need additional incentives[10].

Other measures, specifically independent block holdings, independent directors on the board of directors and quality of audit were also included as control variables. It is expected that presence of independent block holders would be more likely to demand performance based compensation for the CEO, and so would be positively associated with changes in performance based measures of compensation. This was not supported.

Similar arguments also apply to the presence of independent directors on the board of directors. It is expected that the higher the proportion of independent directors on the board the lower the level of total CEO pay (Rankin, 2006). The results support this expectation, and are also consistent with Core et al (1999), Clarkson et al (2005) and Rankin (2006). For the changes in individual components of CEO pay, as expected, significant positive associations were found between changes in total equity based pay and bonus. Firms with a higher proportion of independent directors on the board are more likely to have performance based components in the structure of CEO remuneration.

No significant association between changes in total CEO pay and quality of audit were found which is consistent with Clarkson et al (2005). However, there is a significant negative association between quality of audit and changes in fixed salary and total other benefits and significant positive association with changes in equity-based pay. This suggests that the higher the audit quality, the more likely there is to be longer term performance based remuneration and lower fixed salary and other benefits.

---

[10] The correlation matrix indicates that CEO tenure is positively correlated with the level of CEO ownership.

Firm characteristics are also included as control variables, namely size proxied by the natural logarithm of firms total assets and risk proxied by leverage. It is expected that the bigger the firm is the higher would be the level of total CEO pay. However, the study found a negative but significant association between size and changes in total CEO compensation, in addition to changes in total equity based pay. This is inconsistent with other studies (Rankin, 2006, Merhebi et al, 2005, Core et al, 1999, McKnight and Tomkins, 1999 and Coulton and Taylor, 2002). This could be due to the fact that by scaling the changes in total CEO pay with CEO for the prior period, the study has removed significant size effect. However, positive and significant associations are found between firms size and changes in fixed salary and total other benefits. It could be argued that since these components usually are not performance based and thus are certain, large firms could offer a higher salary to retain the CEO.

Risk could influence CEO pay in both directions, where there is an optimal point beyond which excessive risks would reduce the level of CEO pay, but up to that point risk taking is encouraged (Banker and Datar, 1989). Negative and significant associations are found between changes in fixed salary, bonus and total equity based pay. Although CEO compensation, especially options, are offered as a solution to risk aversion, excessive risk could mean a higher probability of financial distress and the CEO may be penalised though reduction in some remuneration components. It is also possible that leverage is not an appropriate proxy for risk.

Conclusions

Overall, this study found that CEO remuneration is an effective tool in resolving the agency problems between the CEO and the shareholders. Performance-based CEO compensation packages have a positive relationship to firm performance, aligning the interests of CEOs and shareholders. Equity based remuneration is shown to be a superior form of performance based compensation in achieving this objective. The results also suggest that stronger corporate governance promotes greater performance based remuneration, that CEOs with shares in the company are more likely to be paid accounting based bonuses, than other forms of compensation, and that the greater the ownership the lower the compensation, and that longer serving CEOs are more likely to have a higher fixed salary and overall compensation.

The empirical evidence obtained in this study does not support the public criticism levelled at the high level of CEO compensation, but rather suggests that CEOs are rewarded deservedly for an increase in firm performance, rather than on a random basis.

Whilst this study has gone some way to resolve the anomalies of prior studies on Australian firms, there are many factors affecting the relationship between CEO remuneration and performance which cannot be included in all studies. One limitation of the study is value of CEO options and performance rights remuneration are obtained from the firms' annual reports rather than manually calculated. This represents the cost of equity-based remuneration to the shareholder, rather than the value to the CEO. Thus the results can only be viewed from the shareholders perspective. Further, the performance

measures used do not adequately capture the structure of equity based compensation. Whilst shares granted to CEO's may be based on past performance, option grants and rights, although granted on prior performance, could be structured to tie CEO compensation to future firm performance.

3.3 Earnings Management

THE MANAGERS' STRATEGIC CHOICE FOR EARNINGS MANAGEMENT: REAL AND/OR DISCRETIONARY ACCRUALS-BASED EARNINGS MANAGEMENT

Yeonhee Park, SungKyunKwan University
Inman Song, SungKyunKwan University
Kaywon Lee, Chosun University

Abstract:

This study examines whether managers use real activities and/or discretionary accruals as substitutes or complements in managing earnings, and tests the order which managers may strategically utilize in earnings management decisions. Our results shows that managers determine real management(RM) and discretionary accruals(DM) simultaneously, and that the factors determining DM are correlated with RM in opposite direction. The results of this study will provide an additional insight on RM to related regulators and users of the firm's financial information.

Key Words: real activities management, earnings management strategy. earnings management.

Ⅰ. Introduction

Studies on managers' earnings management have been performed for a long time. Substantial prior literatures have provided evidences that managers frequently use discretionary accruals to manage earnings.(Dechow and Sweeney 1995, Jones 1991, Kothari, Leone and Wasley 2005).

Discretionary accruals have been used frequently in managing earnings because discretionary accruals earnings management(DM) can be easily utilized relative to others earnings management tools without direct cash flow consequences. Also, managers can manage earnings using real activities such as sales, production, and discretionary expenses.(Healy and Wahlen 1999, Dechow and Skinner 2000, Fundenberg and Tirole 1995).

Real activity earnings management(RM) will affect directly cash flows because

additional costs may incur. For example, temporary sales increase through price discounts, which is one of RM, will decrease cash flows eventually. It is because the increased sales volumes as a result of the discounts are likely to disappear when the firm increases the sales price in later periods. Also, another way to temporarily boost sales for increasing earnings is channel stuffing, which may increase accounts receivables. These kinds of sales management activities will lead to lower cash flows in current period given the normal sales levels.

Another example for RM is overproduction. Firms may produce more than necessary in order to increase earnings. That is, when managers produce more units, they can spread the fixed overhead costs over a larger number of units, thus lowering fixed costs per unit. As long as the reduction in fixed costs per unit is not offset by any increase in marginal cost per unit, total cost per unit will decline. This will decrease reported cost of goods sold(COGS), and the firm can report higher operating margins. However, the firm may still incur other production and holding costs, which will lead to higher annual production costs relative to sales and lower cash flows from operation given sales levels.

Discretionary expenditures include R&D, advertising expenses and SG&A expenses. Managers can increase current period earnings by reducing such expenses. If managers reduce such discretionary expenditures, these will be lower given sales levels. Also if such expenditures have been paid in cash, it could lead to higher current period cash flows.

The focus of this paper is to find whether RM and DM are performed simultaneously or sequentially in managing earnings. Also, we peruse to examine whether factors, which are known to influence DM, will affect managers' RM.

This study is important for two reasons. First, as mentioned by Fields, Lys and Vincent(2001), examining only one earnings management techniques at one time cannot explain the overall effect of earnings management activities. In particular, If managers use RM and DM as a substitute, examining either type of management in

isolation cannot lead to definitive conclusions. Further managers are more likely to use RM or DM as substitute(or combination). Second, factors deterring DM are more likely to lead to RM since this will be associated with managers' accounting choices.

This study will, first of all, test whether RM or DM are determined sequentiality or simultaneously. Also, we will define factors which influence RM or DM to test for whether managers' decisions for DM affect RM decisions, and then we will test the association between these factors and RM(or DM). In addition, this study will examine what will happen in quarterly bases.

In general, DM doesn't affect cash flows directly. However, it is more likely restricted by the rigidity of accounting standards or interested parties who are affected by firms' accounting results. Thus, we adopt Big4 as one of the major restricting factors for DM in our model. This is because prior literatures provide evidence that Big4 is able to restrict DM(Becker, DeFond, Jiambalvo, and Subramanyam, 1998; Francis, Maydew, and Sparks, 1999) and Big4 are more strict in auditing than Non-Big4.

Second factor for DM is leverage ratio. Managers DM may be constrained because interest parties may require more severe audit process for high leverage firms.

Also, additional obvious costs associated with DM is that the abnormal accruals are mechanically reversed in the short-run, reducing earnings in the next period. That is, if managers ability to increase earnings upward in a current period is constrained by DM activities in previous periods.

The last factor constraining DM is the probability to avoid reported losses. IF firms avoided reported losses through DM, they have to report losses in case that the reported earnings is corrected in the following auditing processes.

In addition, for RM we identify such controlling variables. The first controlling variable is a modified version of Altman's K-score(Altman 1996). We use Altman's K-score in our model because firms close to bankruptcy status are more sensitive to RM, which will affect cash flows. Second controlling variable is equipment volume(divided by sales). Manufacturing firms' managers can decrease cost of sales

through over-production without incurring additional expenses. Third controlling variable is a firm's sales ratio to the average sales of industry. The ratio represent the leading position of the firm in the industry, which firms is likely to be constrained by RM since pushing sales for boosting earnings may lead to a considerable level of accounting receivables. Thus, DM or RM may affected by such each proxies, DM are expected to have negative(positive) relation with factors having positive(negative) association with RM.

In addition, some existing literatures analyzed RM and provided evidence that DM on based on the discretionary accruals was decreased with DM changed to RM based on real activity management.(Cohen et al. 2008; Zang 2008)

Korean companies are rely on DM to raise reported earnings or avoid losses in the first 3 quarters of a year and upward DM in the previous quarters tend to be reversed in the fourth quarter. However, there isn't any study testing how RM are performed in quarterly bases. We expect that managers are likely to refrain from using DM to raise earnings in the fourth quarter if they have used DM in the previous 3 quarters of a year. Thus, managers have incentive to report higher earnings in the first 3 previous quarters using DM, which don't accompany with costs. However, they may do relatively more RM in the last quarter since their ability for using DM is now constrained.

Many earnings management studies have investigated DM in various ways, but only a few recent studies used RM. Moreover, this paper may be the first study testing a relation between DM and RM especially on quarterly bases.

The remaining sections of this study are organized as follows. Section 2 presents the related literatures. Section 3 sets hypothesis, describes the empirical specification and sample. Section 4 presents the empirical results, and finally section 5 provides the conclusion of this study.

910

2. Related literature

Managers can use various means for earnings management. Specifically, they can use both discretionary accruals and real activities. Existing literatures provide evidence that managers use discretionary accruals more frequently in managing earnings.

DeFond•Jiambalvo(1994)와 Sweeney(1994) studied the accounting choices and earnings management for firms violating debt covenants. DeFond•Jiambalvo(1994) indicated that managers used discretionary accruals to increase reported earnings in preventing a debt contract violation. Sweeney(1994) also found an evidence that firms were increasing cashflows and earnings to prevent debt contracts violation. Guenther(1994) suggested that managers were manipulating earnings by using discretionary accruals to cut down the corporation tax when tax rates are increasing.

Subramanyam(1996) examined if stock market could price discretionary accruals. He provided evidence on pervasive income smoothing, which improves the persistence and predictability of reported earnings. He also indicated that discretionary accruals help in predicting future profitability and dividend changes.

In addition, Schipper(1991) asserted that managers have incentives managing earnings using discretionary accruals when they wanted to low earnings.

Existing literatures suggested that mangers have used more discretionary accruals for earnings management. However, there are a few studies using real activity as a tool for earnings management. Presently, studies based on RM have shown that mangers may use acceleration of sales or increase production level as a tool for RM methods available to mangers. (Shipper 1991, Healy and Wahlen 1999, Dechow and Skinner 2000, Thomas and Zhang 2002, Roychowdhury 2006)

In fact, mangers are likely to manage earnings by delaying or maintaining discretionary expenditures. That is, they could decrease discretionary expenditures

to meet earnings target or to increase reported earnings.(Baber et al. 1991, Bushee 1998, Dechow and Sloan 1991) Kasznik(1999) also provide evidence that research and development costs(R&D) or advertising expenditures are abnormally lower in the firms whose real earnings is lower than their voluntarily disclosed earnings

Specifically, Roychowdhury(2006) is to develop empirical method to detect real activity management. Also, this paper examine cash flow from operations(CFO), production costs, and discretionary expenses, variables that should capture the effect of real operations better than accruals. Next, this study use these measures to detect real activities management around the zero earnings threshold. He find evidence consistent with firms trying to avoid losses by offering price discounts to temporarily increase sales, engaging in overproduction to lower cost of goods sold(COGS), and reducing discretionary expenditures aggressively to improve margins.

Zang(2007) study whether managers use real and accrual manipulations as substitutes in managing earnings, and study the order that managers make these decisions. Zang(2007) find that managers determine real manipulation before accrual manipulation. This paper use an empirical model that captures the sequentiality of real and accrual manipulations to test the tradeoffs between the two. The results of the broad sample tests are consistent with managers using real and accrual manipulations as substitutes. However, in a small sample test examining firms subject to securities class action lawsuits, Zang(2007) examine whether real and accrual manipulations change over time with changes in litigation risk.

Cohen et al.(2008) document that accrual-based earnings management increased steadily from 1987 until the passage of the Sarbanes-Oxley Act(SOX) in 2002, followed by a significant decline after the passage of SOX. Conversely, the level of real earnings management activities declined prior to SOX and increased significantly after the passage of SOX, suggesting that firms switched from accrual-based to real earnings management methods after the passage of SOX. They find that firms that just achieved important earnings benchmarks used less accruals and

more real earnings management after SOX when compared to similar firms before SOX. In addition, they provides evidence that the increases in accrual-based earnings management in the period preceding SOX were concurrent with increases in equity-based compensation.

By existing literature, managers are able to use accruals or real activity to managing earnings of the firm, specifically. Also, they provide that real activity management increase more than accrual-based earnings management after the passage of SOX.

This study differs from previous literatures in the following respects. First, this paper tests whether RM or DM are determined sequentially or simultaneously and whether those decisions are different depending on quarters. Second, we identified several factors, which may affect DM and RM differently and the relation between DM and RM.

The results of this study will provide a insight on RM as a tool means for managing earnings to related regulators and users of the firms' financial information

3. Hypotheses and Samples description

3.1 Hypotheses

Managers are likely to use various methods in managing earnings. Specifically, managers often have used discretionary accruals as a method managing earnings(Dechow and Sweeney 1995, Jones 1991, Kothari, Leone and Wasley 2005). Mangers use discretionary accruals management(DM) more easily because DM does not have a direct cash flow effect. On the other hand, it is likely that DM could be detected more easily by serious auditors.

Also, managers can use sales, production, discretionary expenditures in managing earnings.(Healy and Wahlen 1999, Dechow and Skinner 2000, Fundenberg and Tirole 1995). Real activity management(RM) is less likely to catch by auditors although it affect directly cash flows.

Thus, it is not clear which method managers prefer to use in managing earnings. Manager may choose earnings management methods strategically. First of all, if DM and RM are determined simultaneously/sequentially, earnings management both DM and RM may be used simultaneously or sequentially. Thus, this study set up a following research hypothesis to examine whether DM and RM could be used simultaneously or sequentially

Hy   Hypothesis1:

Discretionary accrual-based earnings management(DM) and real activity earnings management(RM) will be used simultaneously.

In addition, earnings management for RM(or DM) could be affected by the following factors. First, firms audited by Big4 audit firm may be constrained in DM. DM is more likely constrained than RM because such DM may be revealed if the firms are audited through more stricter auditing process, which will be performed usually by Big4 audit firms. Thus, firms audited by Big4 will prefer RM to DM so that their earnings management is not constrained. Second, firms used DM in previous period may be constrained in using DM in next period since DM tend to be revered shortly. In this case managers are more likely to utilize RM.

Further, earnings management for DM may be affected by following factors for RM. Factors for RM are firm's financial health, the percentage of the company's sales to the total sales of its industry, and companies' leadership in the industry. These factors will affect managing earnings for DM. Thus, we set up following research hypothesis to test whether factors for DM(or RM) will affect RM(or DM).

Hypothesis2:
Firms audited by Big4 will manage earnings by using real activities(RM) rather than discretionary accruals(DM).

Hypothesis3:
Firms having larger abnormal accruals at in the previous period will manage earnings using real activities(RM) rather than discretionary accruals(DM).

Hypothesis4: Firms having high financial health index, high ratio of the company's sales to the total sales of its industry are more likely to manage earnings by using discretionary accruals(DM) rather than real activities(RM).

3.2 Research Design

This paper estimate the discretionary accruals using adjust Jones(1991, 1995) model and measurement of real activity management using Roychowdhury(2005) model.

We set up the following simultaneous equation system to test the research hypothesis.

Equation model 1 is the empirical parallel of model developed under the assumption of simultaneity of RM and DM decisions. Since RM and DM are assumed endogenous, we estimate equation system 1 using two-stage least squares. Equation 1 can be identified because the cost determinants in the two equations differ. So, we will test the simultaneity/sequentiality of RM and DM with the Hausman test.

Model 1 : $DM = a_0 + a_1 RM_t + a_2 Big4_t + a_3 AbnDa_{t-1} + a_4 NP_t + a_5 LEV_t + a_6 SIZE_{t-1}$
$$+ a_7 DLOSS + a_8\text{-}a_{12} YR + e$$

$RM = a_0 + a_1 DM_t + a_2 DK\_SCORE_t + a_3 ISLE\_S_t + a_4 NP_t + a_5 LEV_t$
$$+ a_6 SIZE_{t-1} + a_7 DLOSS_t + a_8\text{-}a_{12} YR + e$$

Definition of variables:

DM: Discretionary accruals estimated by adjusted Jones model(1991, 1995)

RM: measurement of real activity management, that is abnormal CFO

Big4: Dummy variable equals 1 if the firm's auditor is a Big4 , otherwise 0

LEV: debt ratio, which is current liability / current asset

NP: Dummy variable equals 1 if reported earnings before managing earnings is positive, otherwise 0 .

$AbnDA_{t-1}$: Discretionary accruals in the previous year

DK_SCORE: Dummy variable that equal 1 if the firm's DK_SCORE is less than median of full sample's K_SCORE, and otherwise 0

ISLE_S: The percentage of the company's sales to the total sales of its industry.

SIZE: Ln(total asset in the previous period)

DLOSS: Dummy variable equals 1 if reported earnings is negative, otherwise 0

The simultaneous equation 1 is constructed to test whether managers determine RM and DM simultaneously or sequentially. If DM and RM are simultaneous, in the DM equation, coefficient of RM may be not significant. On the other hand, if RM is determined before DM, there is no feedback from DM to RM, which means RM should be orthogonal to the error term of the DM equation. In the DM equation, the coefficient of RM will be significant statistically.

IF the Hausman test rejects simultaneity, we further test our research hypotheses using the following recursive simultaneous equation system which captures the sequentially of RM and DM.

Model 2 : $RM(\text{or } DM) = a_0 + a_1 Big4_t + a_2 AbnDA_{t-1} + a_3 DK\_SCORE_t + a_4 ISLE\_S_t + a_5 NP_t$

$$+ a_6 LEV_t + a_7 SIZE_{t-1} + a_8 DLOSS_t + a_9\text{-}a_{13} YR + e$$

Model 2 is set up when RM is predetermined by the cost of RM and DM. On the other hand, the DM equation in the research mode 2 has RM as an independent variable. Under the assumption of sequentially, when managers determine the level of DM, they observe the realized RM. Hence, the RM variable in the DM equation is exogenous.

RM may be affected by factors for RM and DM, DM may be positively(+) correlated with the cost determinants of DM and RM may be negatively(-) with their own factors determinants.

In the research model, dependent variable DM is discretionary accruals estimated using adjusted Jones(1991, 1995). and RM is the measurement of real activity management estimated using Roychowdhury(2006) model. For DM, we identify four such proxies.

The first controlling variable, Big4 is dummy variable that equals 1 if the firm's auditor is one of the Big4, otherwise 0. We include Big4 in the model to test whether

managers manage earnings using real activity management rather than using discretionary accruals because earnings management for DM activity is more likely to constrain comparing to RM activity by auditor.

If managers may manage earnings using RM, coefficient of Big4 will be positively(+) significant in the RM equation, and negatively significant in the DM equation.

Variable LEV equal current liability divided current asset. If auditors may audit severely for firms having high debt ratio, such firm's managers are more likely to manage earnings using RM rather than DM.

Thus, coefficient of LEV will be positive correlation with RM and negative correlation with DM. Dummy variable, NP equal 1 if earnings after earnings manipulation is positive and earnings before earnings manipulation is negative, otherwise 0. If firms which had loss before earnings management use much more RM to avoid loss, NP will be significantly positive correlation with RM and negative correlation with DM.

DA is discretionary accruals in the previous period. If mangers used discretionary accruals previous period, they will be constrained earnings management using DM in the current period. Thus we expect that coefficient of DA will be positive significantly in the RM model and will be negative significantly in the DM model.

Other variables are DK_SCORE, and ISLE_S. DK_SCORE is dummy variable that equal 1 if the firm's DK_SCORE is less than median of full sample's K_SCORE, and otherwise 0. Thus, DK_SCORE will be negative correlation with RM but will be positive correlation with DM. Lastly ISLE_S is ratio of the company's sales to the total sales of its industry.

Within an industry, different firms likely face different levels of competition and therefore, different pressure when deviation from optimal business strategy. Therefore, managers in market leader firms may perceive RM as less costly since the erosion to their firms' competitive advantage is relatively small. Thus, we expect that ISLE_S is negative correlation with RM and positive correlation with DM. Loss is dummy variable to control negative earnings effect and other control variable include

917

firm' size, measured as the log value of total asset previous period.

In this paper, discretionary accruals is estimated with the following model(adjusted Jones 1991, 1995), which is run cross-sectionals for each industry-year.

$$TA_{it}/A_{it-1} = \alpha(1/A_{it-1}) + \beta_1(\triangle REV_{it}/A_{it-1}) + \beta_2(PPE_{it}/A_{it-1}) + \varepsilon_{it} \quad (1)$$

$$DA_{it} = TA_{it}/A_{it-1} - [a(1/A_{it-1}) + \hat{\beta}_1(\triangle REV_{it}/A_{it-1} - \triangle REC_{it}/A_{it-1}) + \hat{\beta}_2(PPE_{it}/A_{it-1})] \quad (2)$$

where, TA_{it} = Total accruals at the end of period t

$\triangle REV_{it}$ = Change of salesat the end of period t

$\triangle REC_{it}$ = Change of receivable at the end of period t

PPE_{it} = Property, plant and equipment at the end of period t

A_{it-1} = Total asset at the beginning of period t

ε_{it} = error term at the end of period t

We estimate the measurement for real activity using Roychowdhury(2006) model. Roychowdhury(2006) provided that cash flow, production cost and discretionary expense may be classified into normal and abnormal. Abnormal real activities will be managed discretionally by managers. Thus, we run the following cross-sectional regression equations for every industry and year to estimate abnormal measurements each other.

Following Dechow et al.(1998), we express normal cash flow from operation as a linear function of sales and change in sales in the current period.

$$CFO_{it}/A_{it-1} = a_0 + a_1(S_{it}/A_{it-1}) + a_2(\triangle S_{it}/A_{it-1}) + e$$

$$ABNCFO_{it} = CFO_{it}/A_{it-1} - [a_0 + a_1(S_{it}/A_{it-1}) + a_2(\triangle S_{it}/A_{it-1})] + e$$

where, A_{it-1}: The total assets at the beginning of period t

CFO: Cash flow from operations at the end of period t

ABNCFO: Abnormal cash flow at the end of period t

S: The sales during period t

$\triangle S$: $S_t - S_{t-1}$

Where A is the total assets at the beginning of the period t, S is the sales during period t. And $\triangle S$ is estimated sales at the end of period t minus sales at the beginning of period t. ABNCFO is the actual CFO minus the normal CFO calculated using estimated coefficients from the corresponding industry-year model and the

918

firm-year's sales and lagged assets.

3.3 Samples description

 The periods covered in our analysis are 2001-2006, and <Table 3-1> summarizes the sample selection procedure. Our initial sample consists of 2,562 listed on the Korea Stock Exchange. From this totals, we exclude 496 financial institutions because of the unique procedures required to estimate discretionary accruals or real activities management for these firms. We use the remaining 1,842 observations for this analysis.

\<Table 3-1\> Samples description

4. Empirical Results

4.1 Descriptive statistics and Correlation

 <Table 4-1> provides descriptive statistics on the main variables for this analysis. Panel 1 of <Table 4-1> reports that maximize value of RM is 0.304, minimize value is -0.2991 and median is 0.0008. Median for DM is 0.0030 and mean is -0.001.

Specifically, Median for DM is bigger than median for RM. These statistics is to provide that managers are more likely to manage DM comparing to RM in Korea.

Panel 2 of <Table 4-1> provide that coefficient of correlation between RM and DM is significant negatively at 1% level. Specifically, RM is positively correlation with the factors of DM(Big4 and AbnDA$_{t-1}$). Also, DM is positively correlation with the DK_SCORE which is factor for RM. Incentive variables, NP, is positively correlation with both RM and DM.

Footnote 1) *, **, *** are significant at the 10%, 5%, 1% level , respectively

<Definition of variables>

RM: Real activity management, that is abnormal CFO estimated using Roychowdhury(2006)

DM: discretionary accruals estimated using adjusted Jones model(1991, 1995)

BIG4: Dummy variable if firm which is audited BIG4 audit company is 1, otherwise 0.

Abnda$_{t-1}$: Abnormal accruals,

DK_SCORE: Dummy variable that equal 1 if the firm's K_SCORE is less than median of full sample's K_SCORE, and otherwise 0

ISLE_S: The percentage of the company's sales to the total sales of its industry.

NP1: Dummy variable, that is, it is 1 if reported earnings before managing earnings is positive, otherwise 0 .

LEV: Current debt/current asset

Panel 2 of <Table 4-1> provide that coefficient of correlation between RM and DM is significant negatively at 1% level. Specifically, RM is positively correlation with the factors of DM(Big4 and $AbnDA_{t-1}$). Also, DM is positively correlation with the DK_SCORE which is factor for RM. Incentive variables, NP, is positively correlation with both RM and DM.

<Table 4-2> provides the means for main variables to compare to whether earnings management is different RM from DM base on firm's characteristics.

In the case for firms which are possibility to avoid reported losses, mean of RM is 0.008 and DM is 0.009. However, firms which report losses are -0.028(mean of RM) and -0.043(mean of DM). Also, means of RM and DM for firms which have been audited by Big4 audit company are 0.008 and -0.001. Means of RM and DM for firms which have been audited by Non-Big4 audit company are 0.008 and -0.001.

4.3 Hypotheses Analysis

4.3.1 Analysis results for amounts of earnings management

To test whether managers make RM and DM decisions simultaneously or sequentially, we conduct the Hausman test by regressing DM on the exogenous variables(the factors of DM, incentives, and control variables), the instrument for RM(the predicted value from the first stage regression), and the actual RM. If RM is determined after DM, then the coefficient on the instrumental variable of RM should equal zero. <Table 4-4> reports the results of the Hausman tests for Model 1. Hausman tests reject the exogeneity of RM in the DM regressions(with p-value ranging from 0.001). Also, Hausman test reject the exogeneity of DM in the RM equations. Which means DM(or RM) is correlated with RM(or DM)'s error term. These results indicate that RM and DM are determined simultaneously.

<Table 4-4> Hausman Test for Simultaneity versus Sequentially of RM and/or DM

Model(n=1,842)	RM	DM
Endogenous variables:	Coefficient(p-value)	Coefficient(p-value)
DM	-0.075(0.001)	
RM		-0.078(0.0002)

P_DM	-0.887(0.001)	
P_RM		-0.962(0.0001)
Hausman test

2st-stage adj. R^2(%)	70.46	59.23
p-value for Hausman stat.	0.0001	0.0001

Definition of Variables:

DM: discretionary accruals

RM: abnormal CFO

P_DM or P_RM: the predicted value form the first-stage regression

Given the finding of the simultaneously of RM and DM, we use the recursive regressive Model 2 to test H2-H4. The results are reported in <Table 4-5>.

In the <Table 4-5>, Big4 and Abnda$_{t-1}$ are factors for DM management activity, DK_SCORE and ISLE_S are factors for RM management activity.

H2 predicts that in both models, while Big4 is negatively related with DM, positively related with RM. Consistent with H2, <Table 4-5> shows that RM is significant positively related with Big4 at 10% level. However, DM is insignificant related with Big4, suggesting that firms are reluctant to manager earnings using DM when firms have audited by Big4 audit firm. Also, tests of H3 are indicated by the coefficient estimates for Abnda$_{t-1}$ in both models. If firms used DM activity much more in previous year, they may be constrained using DM in next year. Thus, we expected that managers are more likely to manage earnings using RM activity. Abnda$_{t-1}$ in RM model is significant positively at 1% level as coefficient (t-value) is 0.092(12.81). While in DM model is significant negatively at 1% as coefficient(t-value) is -0.166(-21.63). The results are to support H3.

One of the factors for RM, DK_SCORE, is dummy variable that equals one if the firm's K_ SCORE is smaller than median of full sample's K_ SCORE and zero otherwise. DK_ SCORE in RM model is significant negatively at 1% level as coefficient(t-value) is -0.003(11.69). While in DM model is significant negatively at 1% as coefficient(t-value) is 0.003(10.26). The results are to support H4.

Also, NP and LEV as incentive variables are expected positive coefficient. In the

RM model, NP and LEV are significant positively at 1%, 5% level respectively. In the DM model, while NP is significant positively at 1%, LEV is insignificant. These results indicate that both RM and DM are negatively correlated with their own factors although ISLE_S in the RM model and Big4 in the DM model are insignificant. Also, RM(or DM) is positively correlated with the factors of DM(or RM) although ISLE_S in the DM model is insignificant. Specifically, firms which are able to avoid reported losses by earnings management are likely to using both RM and DM to manage earnings.

SIZE: Ln(total asset in the previous period)

DLOSS: Dummy variable equals 1 if reported earnings is negative, otherwise 0

YR: Dummy variables yearly.

4.3.1 Additional Analysis

To test whether managers make RM and DM decisions simultaneously or sequentially quarterly, we also conduct the Hausman test for each quarters as well as annual.

<Table 4-6> reports the results of the Hausman tests for each quarter. In the panel 1 and panel 3, Hausman tests reject the exogeneity of RM in the DM regressions(with p-value ranging from 0.001 to 0.0001), which means DM(or RM) is correlated with RM(or DM)'s error term. These results indicate that RM and DM are determined simultaneously. On the other hand, in the panel 2, Hausman test fail reject the exogeneity of DM in the RM equations.(with p-values 0.588) In contrast, all of the Hausman tests reject the exogeneity of DM in the RM model, which means DM is correlated with RM's error term. These results indicate that RM and DM are determined sequentially, with RM preceding DM.

5 Conclusions

Substantial studies on earnings management have been performed for a long time. Prior literatures provided evidence that managers frequently used discretionary accruals in managing earnings.(Dechow and Sweeney 1995, Jones 1991, Kothari, Leone and Wasley 2005). However, recent studies provide some evidence that firms may utilize real activities in managing earning even if this will incur additional costs for firms. Therefore, we investigate earnings management through both real activities and discretionary accruals for a broad sample of firms over 2003-2007.

The purpose of this study is to find whether real activity management(RM) and discretionary accruals management(DM) are performed simultaneously or sequentially to manage earnings. Also, we investigate how differently other factors

influencing DM will affect managers' RM decisions.

This result of this study is important for two reasons. First, as mentioned by Fields, Lys and Vincent(2001), examining only one earnings management tool at a time cannot explain the overall effect of earnings management activities. In particular, if managers use RM or DM as a substitute, the examination of either type's earnings management in isolation cannot reach definitive conclusions. Further, managers are more likely to use RM or DM as substitute(or combination). Second, factors that influence DM are more likely to affect managers' RM decision, which may be related to managers' accounting choices.

First of all, this paper tests whether DM or RM are determined sequentiality or simultaneity. Also, we define factors which may influence RM or DM to test for whether DM affect managers' decisions on RM, and we test the relation between these factors and RM(or DM). Lastly, this study tests whether RM or DM are determined differently depending on associated quarters.

The results of this study provide evidence that managers use RM and DM to mange earnings simultaneously. Further results show that RM(or DM) is correlated with the factors for DM(or RM) in an opposite direction although ISLE_S in DM model is insignificant. Also, firms which want to avoid reported losses through earnings management have incentive to manage earnings using both RM and DM.

This study differs from previous literatures in the following respects. First, this study tests whether RM or DM are determined sequentially or simultaneously, and whether managers' decision for RM or DM is different quarterly. Second, we examine some factors associated with DM and RM and their effect on the relation between DM and RM.

The results of this study will provide an insight into the real activities management as a means to manage earnings to related regulators and the users of firms' financial information.

EARNINGS MANAGEMENT BY MEANS OF CHANGES IN ACCOUNTING ENTITIES
－ The Case of Tobu Railway Company －

Yoshihiro Tokuga[11]and Toshitake Miyauchi[12]

Abstract

Companies sometime hide liabilities or losses through changes in accounting entity. Although few textbooks deal with this topic, studying how to use changing entity is very important. In this case, we consider the Tobu Railway Company, which has benefited from industrial policy on several occasions through affecting changes in accounting entity. To ignore this aspect of the company in any analysis, investors and/or analysts attempting to analyze this company would misunderstand it. Through investigating a company's current accounting entity situation, we are sometimes able to quantify the benefits and/or changes attributed to the accounting entity.

The case described below is intended for undergraduate accounting students, graduate students, MBA students, CPAs, security analysts, and other business people who want to *increase their awareness of, and to improve* their business analysis techniques.

Introduction

Although extensive case materials have been produced for Business Analysis education, most of these materials have a North American or European bias, and few have been produced describing the activities of Asian companies. However, for comparative purposes, it is important for students at business schools in Asia to study the accounting behaviors of Asian multinational companies using Asian case materials. We have therefore decided to develop case materials describing the accounting activities of Asian companies.

Companies sometime hide liabilities or losses through changes in accounting entity. Although few textbooks deal with this topic, studying how to use changing entity is very important. In this case, we consider the Tobu Railway Company, which has benefited from industrial policy on several occasions through affecting changes in accounting entity. To ignore this aspect of the company in any analysis, investors and/or analysts attempting to analyze this company would misunderstand it. Through investigating a company's current accounting entity situation, we are sometimes able to quantify the benefits and/or changes attributed to the accounting entity.

The case described below is intended for undergraduate accounting students, graduate students, MBA students, CPAs, security analysts, and other business people who want to *increase their awareness of and to improve* their business analysis techniques.

Tobu Department Stores, which is a subsidiary of The Tobu Railway Company, incurred considerable unrealized capital losses on real estate because it bought a great deal of land during the bubble economy before land prices dropped. In addition, the Tobu Railway Group was at risk of posting considerable losses due to revaluation of fixed assets, which was required because Asset Impairment Accounting would become compulsory from the end of fiscal year 2005 (beginning March 2006). At the same time, the Land Revaluation Law (temporary legislation) was enacted in 1998, which permitted an increase in land valuation for a limited time period. Skillful utilization of this legislation would provide Tobu Railway Group with the opportunity to eliminate unrealized capital losses on land. However, land revaluation under the Land Revaluation Law was restricted to one application per company. Also, when applying the Land Revaluation Law, companies were required to revaluate all owned land; selective revaluation of only land with unrealized capital gains was not permitted. Since the Tobu Department Store subsidiary owned nearly no land with unrealized capital gains, the Finance Department of the Tobu Railway Company considered the possibility of eliminating unrealized capital losses on land for business use by skillfully applying the Land Revaluation Law.

Background

The area serviced by the Tobu Railway Company, which was founded more than 110 years ago in 1897 by the "Railway King", Kaichiro Nezu[13], is shown in Figure 1. Tobu Railway Company primarily services the Kanto Region where it operates routes in 1) the Tokyo Metropolis and eastern Saitama Prefecture (green area[14]), 2) central Gunma and Tochigi Prefectures, and 3) western Chiba Prefecture. By fiscal 2005, Tobu Railway Company had consolidated net sales of 646.3 billion yen and 20,483 employees. Table 1 shows a fiscal 2005 ranking of Japanese railway companies on the basis of net sales; Tobu Railway Company ranks 8th based on sales, and third

---

[13] Kaichiro Nezu is often referred to as the "Railway King" for having amassed considerable personal wealth through rehabilitating railway companies that fell into financial difficulty. He also undertook education projects to return to society profits generated by his railway business activities and opened Musashi University and Musashi High School.

[14] The word "Tobu" in Tobu Railway means "Eastern Musashi". It is derived from "Musashi," the former name for the area consisting of present-day Tokyo and Saitama Prefecture.

among railway companies that have routes in the Kanto Region (company names shown in italics).

≪Figure 1≫ Service Area of the Tobu Railway Company

In addition to railways, the Company consists of a multifaceted corporate group that has operations in the leisure, real estate development, and retail distribution business sectors. Specifically, these operations consist of: 1) the transportation business, including rail, bus, and taxi services; 2) the leisure business, including tourism and hotels; 3) the real estate business, including property subdivision and rental; and, 4) the distribution business, including department stores located primarily in front of Tobu train stations.

These four businesses are all closely related, and the business model employed by the Tobu Railway Company is based on increasing customer traffic by encouraging railway use. Specifically, the business model promotes the use of railways through the development and operation of amusement facilities, department stores, and residential

properties near train stations; people use these facilities because of their proximity to

Figure 2 shows the breakdown of the company's activities in each business segment with respect to revenue and operating profit. The pie charts show the railway and distribution businesses [15] to be the core businesses of the Group, accounting for approximately 70% of the revenue base. They also show that the railway business alone accounts for approximately 60% of the operating profit of the

---

[15] Since the products handled in the distribution business (Tobu Department Store) have high unit prices, revenues from this business segment are high.

company. It should therefore come as no surprise that the Tobu Railway Group makes extensive areas of land in all of its business activities, particularly for the core railway (Tobu Railway Company) and distribution businesses (Tobu Department Store).

The Accounting Problem

In Japan, the implementation of asset impairment accounting in accordance with the Accounting Standards for Impairment of Fixed Assets was only made obligatory from the fiscal year ending March 2006. At the time asset impairment accounting was implemented, in cases where the profit potential (including the land disposal amount) of a fixed asset (plants, land, etc. owned by a company) decreased and the prospects for recovery of the invested funds disappeared, the company was required to record this loss as the difference between the discounted present value of expected future cash flow generated by the fixed asset and the book value. On the other hand, a company was not permitted to increase its valuation of fixed assets for which profit potential had increased. The implementation of asset impairment accounting therefore posed a major problem for the Tobu Group given its considerable land holdings. In particular, Tobu Department Stores had unrealized capital losses on land of fully 50.0 billion yen (equivalent to the total consolidated net income for 5 to 10 years). The Tobu Railway Company realized that Tobu Department Stores alone would incur considerable impairment losses if the company failed to deal with unrealized capital losses before fiscal year-end and the introduction of impairment accounting.

In anticipation of the potential difficulties associated with the introduction of the asset impairment accounting system, the government enacted the Land Revaluation Law in March 1998. The Land Revaluation Law permitted revaluation of land for business use at market prices by financial institutions and ordinary business corporations. However, the law, the purpose of which was to increase the sustainability of financial institutions, especially banks and to improve the corporate management environment, limited companies to only one revaluation of land to market prices. Corporations that applied the law were able to select one of five measures of market price: 1) the posted land price, 2) the benchmark land price as given in the National Land Use Planning Act, 3) the assessed value of fixed assets, 4) the *roadside land price* used for the assessment of *inheritance tax*, and 5) the appraised value by a real estate appraiser. The law required companies to record up to 60% of the difference between the market price and book value as the land

revaluation difference for use as shareholders' equity (refer to the Appendix for a detailed description of the accounting treatment). There were two important considerations at the time of implementation of the Land Revaluation Law: 1) a company could only revalue land once, and 2) a company had to revalue all of the land that it owned. (In other words, a company could not selectively revalue land from which unrealized capital gains had been generated.)

Figure 3 depicts the implementation of the Land Revaluation Law and the implementation of the Accounting Standards for impairment of fixed assets over time. On the one hand, the time limit for the implementation of the Land Revaluation Law was the fiscal year ending March 2002. On the other hand, the implementation of asset impairment accounting was permitted from the fiscal year ending March 2004, and implementation was obligatory from the fiscal year ending March 2006 onward. That is to say, if Tobu Railway wished to avoid recording an impairment loss at the time asset impairment accounting was implemented nationally, then it would be necessary to implement the requirements of the Land Revaluation Law by the end of the fiscal year ending March 2002 in order to reduce, as far as possible, unrealized capital losses on land for business use[16].

≪Figure 3≫ Time Limits of the Law and Accounting Standard Implementation

Aims

The objectives of the Tobu Railway Group's Finance Department at the time of implementation of the new accounting measures were as follows:

---

[16] Other companies also postponed the introduction of impairment accounting and strategically utilized the Land Revaluation Law. In the fiscal year ending March 2002, 280 companies revalued land according to the requirements of the Land Revaluation Law. A total of 453 companies revalued land using the Land Revaluation Law during the period leading up to the fiscal year ending March 2002.

≪**Figure 4**≫　**Land Ownership Structure of the Tobu Railway Group**

(※) Parcel a: land having unrealized capital gains / Parcel b: land having unrealized capital losses

1. To avoid incurring a substantial loss;
2. If possible, to achieve a year-on-year increase in profit; and
3. Selection of a method that would not have a major impact on earnings, taxable income, etc.

The most important consideration related to the implementation of the Land Revaluation Law by the Tobu Railway Group as a means of eliminating unrealized capital losses on land for business use was the legal requirement to revaluate *all* of the land owned by a corporation. Figure 4 shows the land ownership structure of the Tobu Railway Group. It can be seen that, whereas most of the land held by the parent company, Tobu Railway Company, had unrealized capital gains, Tobu Department Store only owned land having unrealized capital losses. This meant that the elimination of unrealized capital losses would therefore be impossible with this organizational structure, even if the requirements of the Land Revaluation Law were followed.

In response, Tobu Railway Company devised the plan shown in Figure 5, which involved selecting land owned by Tobu Railway Company with unrealized capital gains

≪**Figure 5**≫   **The Creation of a New Entity through the Contribution of Land in Kind**

(※) Parcel a: land having unrealized capital gains

Parcel b: land having unrealized capital losses

(Parcel a2), and then donating this land to a newly-established company formed through a merger with Tobu Department Store.[17] Since the unrealized capital gains and losses would correspond (Parcel a2 and Parcel b2 would correspond), satisfaction of the requirements of the Land Revaluation Law following the merger would make it possible to offset unrealized capital losses using unrealized capital gains.[18] Although the Land Revaluation Law required the revaluation of all of the land held by a corporation, the creation of a new accounting entity through the contribution of land in kind would make the partial utilization of unrealized capital gains on land possible.

Tobu Railway Company devised a plan to use this technique at the start of the new financial year in April 2000 to eliminate unrealized capital losses on land incurred by the companies in the group, including Tobu Department Store. Figure 6 shows the

---

[17] Tobu Railway Company used the pooling of interest method as an accounting procedure for business combination. As no accounting standard for business combination existed at the time in Japan, there was no need to satisfy particular requirements at the time of equity pooling; it was left to the discretion of companies as to whether or not they wished to adopt either the equity pooling method or the purchase method.

[18] Under Article 51 of the previous Corporation Tax Law and Article 93 of the previous Corporation Tax Law Enforcement Regulations, which prescribed accounting treatment concerning the establishment of subsidiaries by means of contributions of land in kind, in the case where a company established a subsidiary in which it owned 95% or more of the shares and had a controlling interest, transfers using the book value of the land as an equity contribution were permitted.

planned corporate organization required to achieve this. The plan was for Tobu Railway Company to establish three types of subsidiary - a distribution company, a hotel company, and a company for other business activities - and providing these with land (Parcel a1, Parcel a2, and Parcel a3) with unrealized capital gains owned by Tobu Railway Company as contributions in kind. Tobu Railway Company would then merge the companies having unrealized capital losses on land into the new subsidiaries. The plan was thus to deal with unrealized capital losses on land by applying the Land Revaluation Law to the three new subsidiaries (Tobu Commerce, Tobu Hotel Assets, and Tobu Integrate) after implementing the mergers.

However, for the fiscal year ending March 2001 (fiscal 2000), the unrealized capital losses on land owned by Tobu Department Stores increased beyond initial projections, and it became highly unlikely that these losses could be offset using only the unrealized capital gains on land from the new distribution subsidiary (Tobu Commerce). In response to this situation, in its settlement of accounts for the fiscal year ended March 2001, the Tobu Railway Group abandoned the idea of newly established subsidiaries receiving contributions in kind and applied the Land Revaluation Law to the three new subsidiaries without implementing subsidiary mergers. That is to say, the settlement of accounts for the fiscal year ending March 2001 (fiscal 2000) passed with no pooling of unrealized capital gains on land in the new subsidiaries (Figure 7). Since the difference

≪**Figure 6**≫   **First Plan for Organizational Restructuring**

(※) Parcel a: land having unrealized capital gains / Parcel b: land having unrealized capital losses

in land revaluation amounted to approximately 81.8 billion yen in the consolidated financial statements for that fiscal year, a simple estimate suggests that the Tobu Railway Group implemented a write-up under the Land Revaluation Law equivalent to unrealized capital gains of approximately 136.3 billion yen[19]. Then, in preparation for the fiscal year ending March 2002 (fiscal 2001), the deadline for implementation of the Land Revaluation Law, Tobu Railway Group continued to search for ways to offset the unrealized capital losses on land carried by Tobu Department Stores. After the new

≪**Figure 7**≫   **Modification to the First Plan for Organizational Restructuring**

fiscal year began in April 2001, Tobu Railway Company devised a new accounting method for dealing with the issue of unrealized capital losses on land. At that time, the three newly established subsidiaries had already employed the Land Revaluation Law once. Since a company could only use the provisions of the Land Revaluation Law once, these three subsidiaries could not use the Land Revaluation Law again. However, because Tobu Department Store had not previously employed the provisions of the Land Revaluation Law, the Tobu Railway Company implemented the organizational restructuring changes shown in Figure 8 in preparation for the fiscal year ending in March 2002 (fiscal 2001), which was the deadline for the implementation of the Land
Revaluation Law. The restructuring involved first merging the three newly established

---

[19] 81.8 billion yen ÷ 0.6

subsidiaries into Tobu Department Store, and then revaluating the land belonging to the new Tobu Department Stores company.

Simultaneously, Tobu Railway Group then merged other less well performing subsidiaries, which had land with unrealized profits that were insufficient for covering their own unrealized losses, into the Tobu Railway Company (excluding Tobu Department Store), before applying the Land Revaluation Law to manage unrealized capital losses. As a result of these organizational changes, it is estimated that a land revaluation difference amounting to approximately 64.7 billion yen was reversed, and unrealized capital gains of approximately 107.8 billion yen[10] were applied to offset unrealized capital losses, even when the revaluation differences calculated of the Tobu

Railway Company (approximately 34.1 billion yen) were considered.

≪**Figure 8**≫　　**Second Plan for Organizational Restructuring**

---
[10] 64.7 billion yen ÷ 0.6

≪**Figure 9**≫ **Change in Earnings**

million yen

Operating Profit Ordinary Profit Net Profit

Figure 9 shows the changes in the earnings of the Tobu Railway Group. Earnings for the fiscal year ending March 2006 (fiscal 2005), the year of compulsory implementation of asset impairment accounting, showed an operating profit of 47,707 million yen, an ordinary profit of 41,294 million yen, and a net profit of 26,873 million yen. Although impairment loss is an extraordinary loss item that has an impact on net profit, as a result of utilization of the Land Revaluation Law to deal with unrealized capital losses in advance, the Tobu Railway Group limited the impairment loss in fiscal 2005 to 15,010 million yen, avoided recording a large net loss, and instead achieved an earnings increase (equalization of future earnings).

Still, in the fiscal year ending March 2002 (fiscal 2001), in addition to offsetting unrealized capital losses by applying the Land Revaluation Law, the Tobu Railway

≪Figure 10-1≫ Change in Net Profit

million yen

≪Net Profit≫

≪Figure 10-2≫ Net Profit after Eliminating Bias Introduced by Manipulation of Entities

million yen

Net Profit before Applying the Land Revaluation Law

Group recorded significant losses due to the disposal or elimination of non-performing assets, which resulted in the Group recording a net loss for the fiscal year ending March 2002 (fiscal 2001).

942

Figure 10-1 shows the change in net profit only; a financial indicator we selected for

analyzing the impact of Land Revaluation Law implementation. For purposes of comparison, Figure 10-2 shows the projected change in net profit that would have occurred if the Tobu Railway Group had not applied land revaluation and the unrealized capital loss of approximately 107.8 billion yen had been actualized due to compulsory implementation of asset impairment accounting in fiscal 2005.

It can be estimated that, had the Tobu Railway Group not applied the Land Revaluation

Law, the Group would have posted a net loss of approximately 80.0 billion yen in fiscal 2005.

Next, we will consider how the stock market assessed this change in earnings figures. Figure 11-1 shows change in the monthly price of Tobu Railway Company shares, and Figure 11-2 shows a comparison of the share price for Tobu Railway Company (blue) with the TOPIX (red)[11]. The graphs confirm that the share price increased in the fiscal   year ending March 2006 (fiscal 2005), the year of obligatory implementation of asset impairment accounting, both with respect to raw data and in comparison with the TOPIX. In Figure 10-1 and Figure 10-2 we show the projected business results for the scenario in which the Tobu Railway Group did not deal with its unrealized losses on land through applying the Land Revaluation Law. Supposing that Figure 10-2 provides a true picture of the earnings of Tobu Railway Group, it is possible that the stock market was misled. That is to say, it is conceivable that the share price was decided on the basis of the

≪Figure 11-1≫　Change in Monthly Share Price of the Tobu Railway Company

---

[11] TOPIX is an abbreviation for Tokyo Stock Price Index, a share price index calculated as a weighted average using the magnitude (the total market value) of the share prices of all companies listed on the First Section of the Tokyo Stock Exchange.

≪**Figure 11-2**≫ **Comparison of Tobu Railway Company Stock Price and TOPIX**

treatment of unrealized capital losses even though the company's performance had not actually changed in reality.

Learning Objectives

Four lessons can be obtained from this case study:

1. Earnings can be manipulated by changing entities and the scale of the manipulations.

2. The details of actual discretion with respect to accounting earnings can be demonstrated.

3. Bias introduced by actual discretion can be eliminated from accounting figures.

4. The likelihood of whether share mispricing has occurred can be assessed by collating accounting figures after bias correction with the evaluation of the stock market.

Questions

1. If the Tobu Railway Group desired only to realize unrealized capital gains on land, several other approaches are conceivable. Consider what other methods are available. Consider also the reasons for the adoption of the Land Revaluation Law in this case rather than other methods.

   i) If the Tobu Railway Group had adopted the purchase method at the time of the merger with newly established subsidiaries by means of contributions of land in kind, land revaluation without implementation of the Land Revaluation Law would have been possible.

Goodwill amounting to tens of billions of yen would have been recorded, and amortization of the goodwill would have become a drag on future earnings.

   ii) The sale and repurchase of land with unrealized capital gains would have made land revaluation possible.

   It would have been difficult to find a buyer, and profit on the sale of land and taxable income would be generated in the fiscal year of the sale (i.e. at a time when such a sale would not correspond to future impairment losses).

2. What do you think of the proposition, "The unrealized capital losses could have been eliminated if all subsidiaries had been merged into Tobu Railway Company and the Land Revaluation Law had been applied?"

3. A large net loss was recorded in the fiscal year ending March 2002 (fiscal 2001). Might a big bath have occurred? Obtain the annual securities report and discuss this possibility.

4. The railway industry is a regulated industry. Could the political costs hypothesis not apply here as motivation for recording the enormous loss mentioned in 3 above? Through a discussion of what the political costs hypothesis is, examine whether the receipt of government subsidies or an increase in railway fares occurred.

Appendix

   It is said that implementation of the Land Revaluation Law enabled corporations to deal with unrealized capital gains and unrealized capital losses on land with no impact on the profit and loss statement. We journalize this below using a hypothetical example.

[Example]

   Tobu Railway Company owns two parcels of land, Parcel A and Parcel B, and has applied land revaluation to the two parcels. The acquisition cost of Parcel A and Parcel B, and the market price of the land at the time of revaluation are shown below:

	acquisition cost	market price	difference
Parcel A	500	800	+300
Parcel B	700	500	- 200

Time of Implementation of the Revaluation Method

   ＜Revaluation of Parcel A＞

Debit : Land   300 ／ Credit : **Land revaluation difference   180**
                                        （Added to shareholders' equity）
                                        Deferred tax assets liabilities land
                                                 related   to   revaluation
                                                        120

   ＜Revaluation of Parcel B＞

Debit : **Land revaluation difference   120** ／ Credit : Land   200
        （Subtracted from shareholders' equity）
        Deferred tax assets related to
             land revaluation   80

   ＜Combined Journal Entries＞

| Debit: Land | 100 | Credit: **Land revaluation difference** | 60 |
| Deferred tax assets related to land revaluation | 80 | Deferred tax assets liabilities related to land revaluation | 120 |

At the time of Parcel A revaluation, 60% of the unrealized capital gain is recorded as an increase in shareholders' equity (added to the land revaluation difference account), and 40% is treated as an increase in liabilities. At the time of Parcel B revaluation, 60% of the unrealized capital loss is recorded as a decrease shareholders' equity (decrease in the land revaluation difference), and 40% is treated as an increase in assets. That is to say, by pairing up Parcel A, which carries an unrealized capital gain, with Parcel B, which carries an unrealized capital loss, and applying the Land Revaluation Law, it is possible to offset 60% of the unrealized capital loss by means of addition and subtraction to an item in shareholders' equity (the land revaluation difference account).

PROPERTIES OF FINANCIAL ANALYSTS' EARNINGS FORECAST VARIANCE IN GOOD-NEWS AND BAD-NEWS ENVIRONMENTS: THEORY, EVIDENCE AND USEFULNESS

Davit Adut, University of Cincinnati
P. K. Sen, University of Cincinnati
Praveen Sinha, California State University at Long Beach

Draft: June 2009.

Abstract

This study documents that the variance of analysts' forecast of earnings is smaller when the expected or actual news about earnings is good (relative to when it is bad). Together with the observation that variance of forecast is larger for extreme news, this study offers evidence consistent with the theory that larger variance is caused by higher private information of the analysts. An examination over the entire fiscal year provides evidence of earlier consensus building amongst analysts, as measured by reduction in variance over time in the good-news environment. Forecasts of earnings can be improved when variance of analysts' forecasts are used along with its mean. A trading strategy based on the variance of analysts' forecasts earns positive abnormal returns, when conditioned upon the nature of the news.

I. INTRODUCTION AND SUMMARY

Variance of analysts' forecasts [20] of earnings has been variously interpreted as a measure of risk and informational uncertainty in the prior literature. For instance, Imhoff and Lobo (1992) have used it as a firm level

---

[20] The term variance of analysts' forecasts of earnings is used interchangeably with terms variance of forecasts or variance of analysts' forecasts or analysts' forecast variance throughout this paper.

proxy for differences in opinion amongst investors. In a similar vein, Bryan and Tiras (2007) provide evidence that analyst forecasts are a proxy for other information and that higher level of dispersion indicates high information asymmetry. Zhang (2006) also uses analyst forecast dispersion as a measure of information uncertainty. Gebhardt, Lee and Swaminathan (2001) on the other hand, uses variance of analysts forecast as risk. These characterizations are not without problems and possible contradictions. For example, Diether, Malloy and Scherbina (2002) show that higher analysts forecast variance generate a higher level of stock return, thus contradicting the risk interpretation of the measure. Evidence consistent with the interpretation of informational uncertainty has been provided by many studies such as Diether et al., (2002) and Han and Manry (2000) who document that firms with higher variance of analysts' earnings forecast have relatively lower future stock returns and ROE. In another important paper, Easterwood and Nutt (1999) document that either extreme good news or extreme bad news is associated with increased uncertainty about earnings. Consistent with Easterwood and Nutt (1999), Gu and Xue (2007) document that variances of analysts forecasts are indeed higher for extreme good news and bad news, thus confirming the characterization of informational uncertainty. However, no direct evidence of informational uncertainty has been documented so far.

Theoretical models strive for rational explanations (Trueman 1990; Verrecchia 1983; Dye 1985) and empirical studies provide documentation (Chambers and Penman 1984; Givoly and Palmon 1982; Kothari et al, 2007) that good news about corporate performance comes out earlier than the bad news. In the context of annual earnings, the implications of later arrival of bad

news could be that of higher informational uncertainty, increased private information acquisition by individual investors and financial analysts, and increased variance in analysts' forecasts of earnings for bad news. In this study, we investigate and offer evidence that the variances of analysts' forecasts are systematically different in Good News and Bad News environment and how the extent of good and bad news may affect such varinces[21] Following the measures developed by Barron et. al. (1998) we also offers evidence that such differential in variance can be explained by the underlying information environment of public vs. private information of analysts. We also examine if the variance of analysts' forecasts differ systematically during the fiscal year for good-news and bad-news environments and for the different amount of good or bad news. Finally we also examine the economic significance of such differential variances in connection to earnings forecasts and future stock returns.

More specifically, this study examines the level and change in the variance of analysts' forecasts over the fiscal year under good-news and bad-news environments preceding earnings announcement. It uses *four* definitions of good-news and bad-news events– two *ex ante* definitions and two *ex post* definitions. For each definition, the variance of analysts' forecasts of earnings is compared at various points of time prior to the annual earnings announcement to answer the following four research questions: First, is the variance of analysts' earnings forecasts significantly different for forecasts associated with good and bad earnings news, and if so, how does it differ

---

[21] Payne and Robb (2000) have used a reverse argument that lower variance of analyst forecast would be a motivating factor for managers to expend extra effort to meet market expectations. Hence a "good news" by way or meet or beat earnings forecast is more likely to follow a lower forecast variance.

across different levels of good and bad news? Second, does the differential in variances can be explained by the amount of private v. public information with analysts? Third, does the variance of analysts' forecasts changes differentially and predictably over the fiscal year in good-news and bad-news environments? Fourth, , does the variance of financial analysts' earnings forecasts explain cross-sectional variation in the level of earnings based on expected news (good-news or bad-news) in earnings? Finally, do arbitrage portfolios based on the analysts' forecast variance *and* the nature of expected underlying news generate positive abnormal stock returns? In this final test we confirm the results of Diether, Malloy and Scherbina (2002) and refine their results to show that the interaction of the nature of news and the forecast variance generate an even higher level of stock return.

Our empirical findings are that after controlling for firm, year, and pre-earnings announcement period (quarter), the variance of analysts' earnings forecasts is smaller when there is good-news about earnings. We also confirm the Gu and Xue (2007) results that variances of analysts forecast is greater when the underlying news is extreme. We show that after controlling for the level of good news and bad news, analysts forecast variance is higher for the bad news variance. Further, using the measure developed by Barron et. al. (1998) we show that a) the amount of private information of analysts are always higher in a bad-news environment and b) the amount of private information is higher when the news is extreme. Thus, higher variance is always associated with the higher private information of the analysts. In addition, the variance in analysts' annual earnings forecasts decreases over time, in part, because of interim disclosure of mandatory information. The

evidence further suggests that the reduction in variance is earlier in the good-news environment, consistent with the view that good news disclosures take place earlier and relatively less information is systematically produced for bad-news announcements.   Consistent with theory, we show that the private information of analysts also decreases over time. At an aggregate level, reported earnings are negatively associated with the variance of the analysts' earnings forecasts, and firms with higher variance have lower earnings and bad news.   Thus, if a higher variance is caused by either the nature of the news (good v. bad) or the size of the news (extreme v. small) our result indicate that on the average, the effect of the nature of the (bad) news, dominate that of the size of the (good) news. , As a result, the market consensus forecast is smaller than the mean of analysts' earnings forecasts when analysts' forecasts variance is higher.   We suggest the use of different adjustment factors in different quarters for forecasts made in good and bad-news environments.   Finally, our study documents that arbitrage portfolios constructed at the end of each quarter on the basis of the variance of analysts' forecasts *and* the nature of the underlying news (good-news or bad-news) generate year-end abnormal returns in the range of *6-10%*.

The issue of information dissemination is important for capital market researchers. The predictive power of the analysts' earnings forecast variance, if any, of the future earnings news at announcements is important for investors and other market participants alike. If information in the variance of analysts' earnings forecasts improves the prediction of earnings, then the market's expectation of earnings should assign a weight to this measure. To the extent the market fails to do so, it provides an opportunity to earn

abnormal returns around future earnings announcements and to develop better earnings forecasts. The finding of this study, that the relative disclosure timing of good-news and bad-news (Kothari et al., 2007) has differential implication on the variance of analysts' forecasts, make several important contributions to the literature. *No* prior study has examined and documented that *both* (a) the variance of analysts' earnings forecasts, and (b) the change in the variance of analysts' earnings forecasts over the fiscal year, vary systematically for good and bad-news firms and explain the variation through the extent of private v. public information possessed by the analysts. The finding that the variance of analysts' earnings forecasts contains information that can be used to improve the prediction beyond the consensus analysts' forecast is also not present in the prior literature and has direct implications for *all* capital market studies using consensus analyst forecast as market earnings expectation. Finally, though it has been documented that the variance of analysts' earnings forecasts can be used to generate subsequent abnormal monthly returns (Diether et al., 2002), our results indicate that these abnormal returns are driven by firms with good and not bad-news. Furthermore, by forming portfolios at different points of time, this study documents that the variance of analysts' forecast has information that can be used as early as the first quarter of the fiscal year to generate abnormal returns based on expected earnings news.

II. HYPOTHESES DEVELOPMENT

Information Arrival in Good-News and Bad-News Environments

Theoretical arguments support managerial incentives to delay the announcement of bad news. In a model that makes information manipulation

costly, Trueman (1990) shows that a strategic manager may delay releasing bad news to receive additional information that could improve his or her ability to judge the costs and benefits of information manipulation. Furthermore, if disclosure leads to proprietary costs, information gets released only if the benefits exceed the costs (Dye 1985; Verrecchia 1983). Non-disclosure can represent an extreme form of disclosure delay. Managers also have incentives to build their personal or corporate reputations to create a "resolution preference" that encourages them to hasten the delivery of good news and postpone bad news (Hirschleifer 1993). Finally, the manipulation of information is time consuming and bad news is always manipulated to the greatest extent possible before its release, which may lead to the delay. A simple explanation for this intentional delay posits that the passage of time is of value to a manager because interim actions and unforeseen events might ameliorate the consequences of the bad-news event.

Overwhelming empirical evidence provides corroborating evidence that good news about corporate earnings comes out early, and bad news comes out later (Chambers and Penman 1984; Givoly and Palmon 1982; Kross and Schroeder 1984; McNichols 1988; Mendenhall and Nichols 1988; Patell and Wolfson 1982; Penman 1984; Begley and Fischer 1998; Kothari et al. 2007). Kothari et al. (2007) consider this as a career concern of the manager because such disclosure strategy has the potential to alter management compensation. They rightly observe that in cases of recent scandals managers explicitly withheld bad news from outside investors and such

behavior reinforces the belief that managers' private incentives significantly influence the characteristics of corporate disclosures.[22]

The literature points to other motives for timing disclosures. For instance, managers may delay the release of bad news to benefit from the opportunity to exercise stock options. Several studies (Baginski et al., 1994, Yermack, 1997, and Aboody, Barth and Kasznik, 2004)) have shown that managers accelerate bad news and/or withhold good news in the period immediately preceding the option grant dates to lower the exercise price of the options thus increasing the value of their option grants. Other studies (Kasznik and Lev (1995), and Skinner (1994, 1997)) show that managers have a propensity to forewarn analysts of losses (bad news) to prevent increased exposure to litigation risk. This advance notice, however, refers only to a warning prior to the statutory release of the information and does not suggest communication at the inception of the bad-news event or that it would appear earlier if the firm had good news to report.[23] Other explanations for delay include audit complexities associated with bad news, delays by smaller firms (that have more bad news on average), and industry practices that cause more bad news during the test period. None of these explanations receive strong empirical support over time (e.g., Givoly and Palmon, 1982). To summarize, earlier as well as more recent studies (Begley and Fischer, 1998, Kothari, 2007) provide evidence that after considering various

---

[22] A more appropriate but extreme example of the value of the passage of time is the following story retold by Ro Verrecchia (Verrecchia 1983). When sentenced to death by the King, a knave offers to teach the King's horse how to talk in a year's time. He explains later to his friends, "Within a year anything can happen, the King may die, the horse may die, or the horse may even learn to talk."

[23] It seems that under an experimental setting, analysts seem to believe that disclosures are downwards biased and managers have a definite pre-announcement strategy (Tan et al. 2002).

incentives to manage news releases, managers release good news earlier than bad news.

Analysts Incentive & Interactions in Good News and Bad News Environments

Empirical evidence indicates that financial analyst incentives differ in analyzing firms with good news versus bad news. McNichols and O'Brien (1997) show that financial analysts are generally reluctant to be the first bearers of bad news and may choose to delay their information release. In extreme cases of bad news, financial analysts may drop the firm rather than repeatedly release unfavorable news. Womack (1996) and Michaely and Womack (1999) provide similar evidence when analysts face conflicts of interest arising from underwriting relationships. Because most analysts issue buy-side recommendations, they do not want to antagonize their clients by possibly prematurely "crying wolf". Furthermore, firms experiencing poor performance may have an inherently higher level of uncertainty, whose resolution takes longer, which would imply a later release of information.

The notion that the nature of the news affects the communication, interaction, and information flows among managers and analysts is well documented in empirical research. Burgstahler and Eames (2006) and Matsumoto (1998) provide evidence that firms manage both earnings (upwards) and forecasts (downwards) in their effort to create good news by meeting or beating analysts' expectations. They further argue that firms manage their forecasts by deliberately biasing their communications with analysts to lower forecasts. Such forecast management can take many forms,

including but not limited to calls to analysts, and public "pre-announcements" of bad news (Kasznik and Lev, 1995, Skinner, 1994 & 1997, Bamber and Cheon, 1998) at least in qualitative terms. Firms releasing good news could be more precise than for bad news. For example, a good-news release could refer to improvements in earnings per share, whereas a bad-news release might offer only general terms (Skinner 1994). Brown (2001) contends that managers' incentives to manage earnings and analysts differ dramatically when they report losses versus profits. When reporting bad news, managers do not forewarn analysts. Degeorge et al. (1999) demonstrate the decreased (increased) communication among firms and analysts when firms report losses (profits), perhaps to reduce (increase) the frequency of bad news (good news). [24] Taken together, these characteristics suggest significant differences in good and bad news forecast environment, which can influence the properties of analysts' forecasts.

Impact of Informational Characteristics on the Variance of Analysts' Forecasts

Empirical studies document that financial analysts revise and update their forecasts in response to quarterly reports (Abdel-khalik and Espejo, 1978), management forecasts (Jennings, 1987), other analysts' forecasts (Stickel, 1990), and changes in stock prices (Brown et al., 1985). Changes in the frequency and nature of interactions with managers can influence the properties of analyst forecasts. Until recently, analysts routinely conducted informal discussions with managers on a regular basis. However, with the

---

[24] Lev and Penman (1990) find that earnings forecasts, as a rule, differentiate firms with "good" annual earnings from other firms and that, on average, forecast news is "bad".

passage of SEC Regulation Fair Disclosure, this communication is not possible anymore.

Researchers have used the variance in analysts' forecasts to measure earnings predictability and the degree of consensus in the market. Imhoff and Lobo (1992) show that the *ex ante* uncertainty of earnings predictability, as captured by the variance in analysts' forecasts, correlates with the earnings response coefficient. Daley et al. (1988) indicate that the variance in analysts' forecasts correlates with the magnitude of unexpected earnings and, by implication, the ex-post variance of realized earnings. They also show that the variance in analysts' forecasts captures the *ex ante* variance of stock prices, similar to Patell and Wolfson (1979). Ziebart (1990) uses the variance measure as a surrogate for market belief consensus, which correlates positively with trading volume.

Several studies argue that variance of analysts' forecasts capture the nature of information environment that determines forecast accuracy. Brown, Richardson and Schwager 1987 construct their measure of forecast accuracy of analysts by comparing the variances of tome series forecasts and analysts forecasts. Other studies document that the accuracy of analyst forecasts is correlated with the variance (coefficient of variation/dispersion) of the analysts' forecasts (Elton, Gruber and Gultekin 1981,). Gu and Xue (2007) show that the variance of analysts' forecasts is much larger when the news is either extremely good or extremely bad. They show a U-shaped relationship between news and variance, but fail to identify that the U shape is asymmetric with larger steepness on the left (bad news) than the right (good news). A comparison of the relative magnitude of variance under good news and bad

news provides additional insights on the role of news on analysts' earnings forecast variance that our study seeks to exploit.

Definitions of Good News and Bad News Environments

Degeorge et al. (1999) consider three earnings thresholds that induce income manipulation to generate good (bad) news: meet or beat (not meet or beat) prior performance, report profits (losses), and meet or beat (not meet or beat) analysts' expectations. Because our focus is on the properties of analysts' forecasts, we could only use the first two measures. We contend that consensus (mean) forecasts (the threshold for meeting and beating expectation) and variance of analysts' forecasts may not be independent. We define *ex post* good and bad news as follows:

A. A reported increase in earnings from last year is good news, and a reported decrease is bad news.

B. A reported profit is good-news, and a reported loss is bad news.

We also consider *ex ante* definitions of good and bad news. Unlike the ex post grouping, which is based on realized earnings, the *ex ante* grouping depends on whether the expected news about the firm is good or bad. Following our earlier arguments and our definition of good-news and bad-news scenarios, we expect the variance of analysts' forecasts to be smaller in the case of good-news announcements over all, and also to be so after controlling for the level of the good (bad) news.

H1: *The variance of analysts' forecasts of annual earnings is smaller in good-news environments.*

Our interpretation of the variance in analysts' forecasts, though consistent with the literature, also posits that good and bad news information

environments lead to two distinct distributions of analyst's forecasts characterized by differential variances. We conclude that bad-news leads to a decrease in the amount of information available to analysts at the time of their forecasts. Thus, the forecast generated by financial analysts in bad-news environments is conditional on relatively less information that is likely to be noisier. The lack of news may also affect the degree of private information available to the analysts and the weights they assign to this information. Following Barron et al. (1998) and Barron et al. (2002), such lack of precision and lack of consensus would lead to a higher variance in analysts' forecasts of earnings in bad-news environments. Thus our second hypothesis follows:

> **H2:** *A smaller (larger) variance of analysts' forecasts of annual earnings is associated with a large proportion of public (private) information with the analysts.*

If consensus building takes place over time, both good and bad-news firms should exhibit a steady reduction of forecast variance over time. This could be partly due to the interim release of the mandatory quarterly earnings reports. Blackwell and Dubins (1962) show that opinions about an unknown event tend to converge as the amount of available information increases. If good-news arrives faster than bad-news, the forecast variance under good news should decrease faster over time than for bad news, at least in the early quarters. Kasznik and Lev (1995) point out that later (fourth) quarter of each year has by far the largest number of analysts' forecasts which suggests an increased rate of information arrival. Therefore, information acquisition (both private and public) is likely to be significantly more in later periods that are closer to the annual earnings announcement. We treat the fourth (later)

quarter information environment differently also because it coincides with the release of annual earnings, which are audited and more closely scrutinized. Accordingly, our hypothesis is:

> **H3:** *(i) The variance of analysts' forecasts of annual earnings declines over the year; (ii) the rate of variance reduction is higher in earlier periods for firms with good-news.*

To further exploit the role of analysts' earnings forecast variance, we examine its ability to predict future earnings. Given Hypothesis 1, the analyst earnings forecasts variance should convey information beyond the mean forecast information. Therefore, analysts earnings forecast variance should play a role in predicting earnings. However, with the passage of time and because good news arrives early, the role of variance should diminish for good-news announcements. For bad-news announcements, analysts earnings forecast variance may continue to play a role until such time when the underlying uncertainty is resolved. *Ceteris paribus*, if higher variances are associated with bad news, then the effect of increased variance on earnings forecasts should be more pronounced for firms with bad-news.

> **H4:** *For a given level of annual earnings forecast, (i) actual earnings are negatively associated with the variance of analysts' forecasts, and (ii) this association is more pronounced in the bad-news environment.*

Finally, we investigate the possible economic impact of differential analysts earnings forecast variance under the two news environments on stock returns. Though Diether et al. (2002) have documented that portfolios formed on the variance of analysts' forecasts can be used to earn positive abnormal returns, we further partition the variance levels by the nature of the expected news, and state Hypothesis 4 as follows:

> **H5:** *(i) For any news environment, the buy-and-hold stock returns will be higher for stocks with smaller forecast variance, and (ii) the largest*

arbitrage return is between the good news-low variance and the bad news-high variance portfolios.

III. DATA

Sample and Variables

We draw our data from three sources: *I/B/E/S*, Compustat, and CRSP, from 1996-2002. We use the *I/B/E/S* detail database for individual analysts' forecasts of annual earnings per share (EPS). This database provides (a) the cusip identifier, fiscal year and the reported EPS of the firm, and (b) analyst's identification code and dated forecast. We obtain quarterly and annual earnings announcement dates from the 2006 *Quarterly Compustat* files. The *Compustat* and *I/B/E/S* databases are merged to create an *initial* sample of firms with availability of both (i) analysts' forecasts, and (ii) quarterly announcement dates. In this *initial* sample, annual earnings forecasts are made at various times, from the beginning of the fiscal year[25] to the annual earnings announcement date. To ensure that a subset of forecasts are conditional on the same earnings information, we classify all forecasts into one of four pre-earnings announcement periods (PEAPs) that roughly correspond to the four fiscal quarters.

The first PEAP includes only those forecasts made *after* annual earnings announcement and *prior* to the announcement of first quarter earnings. When the first quarterly earnings announcement is delayed relative to the prior year's corresponding announcement, we delete the forecast to ensure that all forecasts use the previous year's annual earnings alone, not the inference associated with any delay in the quarterly earnings

---

[25] Jan 1st for firms with December ending fiscal year.

announcement of the current quarter. In the second (third) PEAP, we include only those forecasts made *after* the announcement of first (second) quarter earnings and *prior* to either (1) the date of announcement of second (third) quarter earnings or (2) the expected earnings announcement date (determined by the previous year's corresponding quarterly announcement date), whichever is earlier. Finally, the fourth PEAP includes only those forecasts made *after* the announcement of third quarter earnings and *prior* to the announcement of annual earnings or the expected earnings announcement date (determined by the previous years' annual announcement date), whichever is earlier. Thus, the four PEAPs represent four disjointed time periods, with potential discontinuities, between the two annual earnings announcement dates.

The sample includes all forecasts for a firm in a given PEAP-year. To avoid dependency induced by an analyst issuing multiple forecasts in a PEAP-year, we select only the last forecast of an analyst in each PEAP-year for a firm. Furthermore, we require *at least* four distinct analysts' forecasts in each PEAP-year. To ensure that there are enough years of data for each firm, we retain only those firms that have at least full 7 years of data over the period examined. Finally, we delete firms in the financial services and utilities services industries because these industries are regulated. These sample selection constraints result in a *final* sample with 12,368 PEAP-years for 334 firms. We compute the mean, M_{itp}, and variance, V_{itp}, of analysts' forecasts for each firm PEAP-year.

IV. RESEARCH DESIGN AND EMPIRICAL RESULTS

In this section, we explain and present the multivariate tests of our hypotheses. To ensure that firm-specific factors, such as relative beta risk, size, and industry-specific characteristics, do not drive differences in variances, we include a separate dummy variable for each firm in our specification.   By providing this explicit control, we capture firm-specific differences through the dummy variable coefficients. Because we cover a 10-year period, variations in macroeconomic factors could confound our findings. We control for these time-specific effects by including a dummy variable for each year. In addition, a dummy for earnings quarter was included for tests involving differences across PEAPs.   Unless stated otherwise, all of the specifications tested share these common control variables.

Good News and Bad News Measures

We construct indicator variables corresponding to the two *ex post* and the two *ex ante* definitions of good-news and bad-news. Using definitions A and B, outlined in Section 2, the ex post indicator variable for good-news, GN, is constructed as follows:

A. GN_{it} = 1   if $E_{it} \geq E_{it-1}$ (If current year earnings
            0   otherwise   exceed   previous   year
                                                    earnings)

B. GN_{it} = 1   if $E_{it} \geq 0$ (If profits are reported in
the
            0   otherwise   current year)

BN_{it}, is the complementary indicator variable for bad-news announcements.   In contrast to *ex post* definitions, the e*x ante* definitions proxy for the market's expectation of good-news or bad-

964

news during each PEAP. We compute the mean of all analysts' forecasts in each PEAP as an estimate of the markets' expectation. If the mean of firm i in year t and PEAP p, M_{itp}, equals or exceeds (is less than) that firms' previous years' earnings, E_{it-1}, we infer that the market expects current years' earnings to be higher (lower) than the previous year's earnings. If M_{itp} is equal or greater (less) than 0, we infer the market expectation to be that the firm will report profits (loses). These indicator variables, denoted as C & D, provide *ex ante* version of good news and bad news defined as A and B.

C. GN_{itp} = 1   if $M_{itp} \geq E_{it-1}$ (If current year earnings are

        0   otherwise   expected to exceed previous year earnings)

D. GN_{itp} = 1   if $M_{itp} \geq 0$ (If the firm expects to report

        0   otherwise   profits in the current year)

Under definitions C&D, the news expectation can change from PEAP to PEAP. This allows for the same firm to be classified as expecting good-news in one PEAP and bad news in another. These definitions contrast with definitions A&B, where a firm is classified into the same news category for all four PEAPs of the year.

Descriptive Statistics

In Table 1, we present the industry distribution and descriptive statistics for the sample. Panel A provides evidence that our data is well represented and all of the major industries are included in our sample. As per Table 1, Panel B, total assets (Compustat item #44) vary from \$30,016 million to \$527,715 million, consistent with representation of mostly large firms in the

sample. Average firm ROA, income before extraordinary items (Compustat data item #8) to average total assets, varies from 3.30 to 24.10 percent. The mean (median) return on equity (ROE), computed as the ratio of income before extraordinary items to total stockholders' equity (Compustat data item #60), is 13.31% (13.01%). The mean of earnings per share (Compustat data item #11) is $1.46 and the maximum EPS is $35.00. Market value of equity is calculated by multiplying number of shares outstanding (Compustat data item #15) by the closing price on the 3rd month of the quarter (Compustat data item #14). The mean (median) market capitalization is $15,731 ($4,473) million.

Table 2 presents the variance of analyst forecasts for the two *ex post* and the two *ex ante* definitions of good-news, by year and PEAP. Also presented are the results of the univariate tests of difference in the mean analysts' forecast variances under the good-news and the bad-news environments. Under all four definitions (A-D), our tests indicate that in all 11 yearly comparisons (100%), the variance is smaller for the good-news announcements, with 10 (9) out 11 differences statistically significant at 0.01 level or better for definitions A-C (D). To ensure that these results are not driven by any particular PEAP, we also test for difference in variances in good-news and bad-news environments across PEAPs. For all four definitions, the variance in good-news environments is significantly smaller than the variance in bad-news environments for each PEAP (1-4). Based on this univariate analysis, the variance of analysts' forecasts is significantly smaller for firms expecting good news than for firms expecting bad news for all eleven yearly comparisons and all four PEAP comparisons.

Test of Hypothesis 1 (Association of nature of news and the forecast variance)

As per Hypothesis 1, the variance of analyst forecasts should be *lower* when the current year's earnings convey good news. We test this hypothesis by regressing analyst forecast variance on dummy variables corresponding to good and bad news, after controlling for the firm, year and PEAP effects using the dummy variables (and suppressing the intercept term) as follows:

$$\tilde{V}_{itp} = \sum_{i=1}^{I-1} \mu_i F_i + \sum_{t=1}^{T-1} \sigma_t Y_t + \sum_{p=1}^{P-1} \gamma_p P_p + \beta_1 GN_{it} + \beta_2 BN_{it} + \tilde{\varepsilon}_{itp} \tag{1}$$

where F_i, Y_t, and P_p denote dummy variables corresponding to firms, years, and PEAPs, respectively, and μ_i, σ_t, and γ_p are the corresponding parameters. I, T and P denote the number of firms, years and PEAPs. β_1 and β_2 represent average variance for good news and bad news firms. To make comparisons of analysts' forecasts variance under good news and bad news, a test of the null hypothesis of the equality of β_1 and β_2 is conducted against the directional alternate that $\beta_1 < \beta_2$. Estimation results for (1) appear in Table-3. Due to a large number of parameters in the model, we only present the parameters of interest (β_1 and β_2), but compute F-statistics on the test of equality of the subset of coefficients corresponding to firm, year and PEAP to evaluate the effectiveness of these controls. In each of the estimations of (1) reported in the table, the F-statistics corresponding to the firm, year and PEAP effects were significant, justifying these controls. The results are first presented for the pooled sample, and then separately for each PEAP.

In the estimation involving data pooled over all PEAPS for firms reporting increasing profits (definition A), the coefficient for the good-news

dummy is 0.02 while the coefficient for the bad-news dummy is 0.06. Even though the individual coefficients are not, the difference in these coefficients is significantly different from zero at conventional levels of significance (0.05 or better). Similar findings are obtained when analysis is performed over PEAPS. For PEAP 1 (2, 3, 4) the coefficients for the good news and bad-news dummies are 0.03 (0.02, 0.007, 0.01) and 0.06 (0.05, 0.07, 0.04), respectively. For each PEAP, the magnitude of the parameter estimate of good-news dummy is significantly smaller than that of the bad-news dummy. These results provide supporting evidence for Hypothesis-1. For firms reporting profits, we get similar results and draw the same conclusions. At the pooled level, the coefficient on the good-news dummy is 0.03 which is significantly smaller than the coefficient for the bad-news dummy, 0.14. For PEAP 1 (2, 3, 4) the coefficient for the good news dummy 0.03 (0.03, 0.02, 0.02) is significantly smaller than the corresponding coefficient for bad-news 0.15 (0.16, 0.16, 0.08).

For firms expecting higher profits in the current year compared to previous years' profits (ex ante definition C), the estimated coefficient for the good-news dummy is 0.02 and that for the bad-news dummy is 0.05 for the pooled data. Our test rejects the null hypothesis of equality of these two coefficients at conventional levels of significance (0.05 or better). For PEAP 1 (2, 3, 4) the coefficient for the good news dummy, 0.04, (0.02, 0.01, 0.02) is *significantly* smaller than the corresponding coefficient for the bad-news dummy 0.06 (0.05, 0.06, 0.04) ($p < 0.01$). Similar results are obtained when we consider firms expected to report profits (definition D). For the pooled sample, the coefficient on the good-news dummy is 0.02, significantly smaller

than the coefficient for the bad-news dummy that equals 0.14, and we reject the test of equality at conventional levels of significance (0.05 or better). For PEAP 1 (2, 3, 4) the coefficient for the good news dummy 0.02 (0.03, 0.02, 0.02) is significantly smaller than for the bad-news dummy 0.17(0.20, 0.18, 0.09) at conventional levels of significance (0.05 or better). Collectively, our results provide evidence that the variance of analysts' forecasts is smaller under good news environments.

In order to verify whether the size of the news affect our result, we partition our data into four quartiles for each PEAP and run our tests. Though the quartiles with extreme news have a higher variance than those in the middle, we show that for each comparable quartile, the good news variances are lower than those of bad news. (discuss the table - - to be written))

Test of Hypothesis 2 (More private (public) information with larger variances) (to be written)

Tests of Hypothesis 3 (Variance reduction over time)

Hypothesis-3 suggests that early consensus building occurs when firms expect good news and the consensus building is delayed for bad news. Given faster resolution of uncertainties for good news firms, we expect the rate of decline in forecast variance for good-news firms to be higher than for bad-news firms. We test this by estimating the following equation:

$$\tilde{V}_{itp} = \sum_{i=1}^{I-1} \mu_i F_i + \sum_{t=1}^{T-1} \sigma_t Y_t + \rho_g V_{itp-1} GN_{it} + \rho_b V_{itp-1} BN_{it} + \tilde{\varepsilon}_{itp} \qquad (2)$$

Estimation of equation (2) involves regression of V_{itp} on V_{itp-1} for good- and bad-news firms after controlling for firm and year fixed effects. Because the

lagged variance is a right hand side variable, equation (1) can be estimated using the data for PEAPS 2-4 only. The model is estimated separately for each PEAP because we are interested in the reduction of variance over-time and our predictions vary over PEAPS. In this specification, we expect both ρ_g and ρ_b, to be less than one, consistent with reduction of variance of forecasts over time. A lower value of the coefficient of prior period variance ($\rho\square$, implies a faster reduction of variance over time. We expect ρ_b to be larger than ρ_g in the earlier PEAPS and ρ_b to be smaller than $\rho_{g,}$ in the later PEAPs[26].

Results from the estimation of equation (2) for all four definitions are presented in Table 4. The estimated coefficient of ρ_g varies from 0.37 (PEAP 4, definition C) to 0.74 (PEAP 1, definitions A&C), and that of ρ_b varies from 0.23 (PEAP 4, definition B) to 1.04 (PEAP 3, definitions A&C). All the coefficients are significantly smaller than *one* at the conventional levels of significance (0.01 or better), except for PEAP 3 (under definitions A&C). However, this estimate is not significantly larger than *one* consistent with the view that the variance is not increasing. The conclusion from these results is that the variance either decreases or remains same for each PEAP, for all news types.

To test for the relative rates of variance reduction under good news and bad news scenarios, we compare the magnitudes of ρ_g and ρ_b in each PEAP. For PEAPs two three and four, the respective estimates of ρ_g (ρ_b) are 0.74 (0.67), 0.41 (1.04) and 0.44 (0.27) under definition A, 0.61 (0.77), 0.59 (0.71) and 0.48 (0.23) under definition B, 0.74 (0.78), 0.43 (1.04), and 0.37 (0.26) under definition C, and 0.59 (0.77), 0.48 (0.75) and 0.45 (0.24) under

---

[26] This is because the total reduction of variance is expected to be same for all firms, on average.

definition D. A pair-wise comparison shows that for all four definitions, the rate of variance reduction is significantly higher for good news firms ($\rho_g < \rho_b$) in PEAPs 2 and 3, but the rate of variance reduction is faster for bad news firms ($\rho_b < \rho_g$) in PEAP 4. The only exception is PEAP 2 under definition A in which the variance reduction is faster for firms with bad news ($\rho_b < \rho_g$).

Collectively, the finding is that variance reduces at a faster rate for firms with good news in the earlier PEAPS. However, in PEAP 4, the variance reduces at a faster rate for firms with bad news because consensus is built amongst analysts about the upcoming bad news about the firm either through the private information acquisition and its dissemination in prices or because delay of news is accepted by all analysts as a precursor to the arrival of bad news, or because of voluntary release by the management. These results provide support for our hypothesis.

Tests of Hypothesis 4 (Earnings Predictions)

Hypothesis-4 suggests that actual earnings should be lower when the variance of analysts' forecasts is higher. Furthermore, the association between news and variance is stronger for firms with bad news after controlling for analysts' forecasts, nature of the expected news and the firm and year effects. We test this hypothesis by regressing earnings on the mean and variance of analysts' forecasts of earnings, with a separate parameter for the good-news and bad-news firms as follows:

$$\tilde{E}_{it} = \sum_{i=1}^{I-1} \mu_i F_i + \sum_{t=1}^{T-1} \sigma_t Y_t + \rho_{gp}(M_{itp} * GN_{it}) + \rho_{bp}(M_{itp} * BN_{it}) + \tau_{gp}(V_{itp} * GN_{it}) + \tau_{bp}(V_{itp} * BN_{it}) + \tilde{\varepsilon}_{it} \qquad (3)$$

Table 5 presents results based on two ex ante definitions (C&D). The F-statistics for the goodness of fit of the models are significant for all PEAPs.

The predictive ability of the models also increases over time as adjusted R^2 increases from PEAP one through PEAP four. This finding is consistent with the notion that arrival of news over time explains larger portion of cross-sectional variation in reported earnings. In this specification, ρ_{gp} (ρ_{bp}) are the estimated parameters for the mean forecasts of the firm in PEAP p. An estimate of ρ less (greater) than *one* is consistent with optimism (pessimism) in the forecasts, and $\rho=1$ is reflects no bias in the forecasts.[27] For PEAPs one, two, three and four, the respective estimates of ρ_{gp} (ρ_{bp}) are 0.93 (0.89), 1.02 (0.97), 1.03 (1.04), and 0.97 (0.96) under definition C, and 1.02 (0.76), 1.02 (1.03), 1.00 (1.03) and 1.01 (0.91) under definition D. In each of these pairs, the estimate of ρ_{gp} is closer to one than the estimate of ρ_{bp}, consistent with smaller forecast errors for good news firms in each PEAP for both the definitions. Though no clear predictions are made about changes in ρ_{bp} over PEAPs, pessimism will get embedded in forecasts for firms expecting bad news because of late arrival of news. Under both the definitions, there is optimism for firms expecting bad news in PEAP 1. However, with the passage of time, the optimism changes to pessimism. The coefficient of ρ_{bp} gradually increases from 0.89 (0.76) to 0.97 (1.03) to 1.04 (1.03) when moving from PEAP one to two to three under definition C (D).

For PEAPs one, two, three and four, the respective estimates of τ_{gp} (τ_{bp}), the coefficients for the variance of analysts' forecast variable for firms expecting good (bad) news, are -0.05 (-0.09), -0.01 (-0.11), -0.04 (-0.14), and 0.005 (-0.17) under definition C, and -0.08 (-0.17), -0.07 (-0.13), -0.07 (-0.38), and -0.001 (-0.12) under definition D. For the bad (good) news firms, all (7

---

[27] We also estimate a more conventional specification of forecast error model by subtracting the mean forecast from the actual earnings, and regress it on the remaining variables in equation (3). The results (not reported) provide similar interpretation.

out of 8) estimates are negative, with seven (four) out of eight significantly less than zero. These finding are indicative of smaller earnings when the variance is higher, especially for firms with bad news. A temporal analysis of the role of variance in bad news scenarios indicates that the role of variance keeps getting more prominent as evidenced by the increase in the absolute value of τ_{bp} (from -0.09 to -0.11 to -0.14 to -0.17) under definition C with three out of four estimates significantly smaller than zero. Under definition D, all four estimates (-0.17, -0.13, -0.38 and -0.12) are negative and significant, consistent with variance playing a role in all time periods.

A pair-wise comparison shows that the absolute value of τ_{gp} is always smaller than the absolute value of τ_{bp} with four out eight differences significantly smaller than zero. Collectively, these results point to smaller earnings when the variance is high, especially for firms expecting bad news. These results provide support for our hypothesis that high variance is associated with lower earnings and that variance plays a stronger role for firms with bad news. In sum, we conclude that variance is an important factor in predicting earnings and that there are significant differences in the role of forecast variance in good-news and bad-news scenarios.

Test of Hypothesis 5 (Portfolio Returns)

To examine the economic significance of the improvement in earnings forecasts by incorporating forecast variances, arbitrage portfolios are constructed on the basis of the nature of the news and the variance of analysts' forecasts. The abnormal returns from these arbitrage portfolios become another basis for evaluating the usefulness of the information in analysts' forecast variance. Since our evidence suggests systematic

973

difference of forecast variance as early as the first PEAP, we begin construction of our arbitrage portfolio based on the variance of forecasts at the end of first PEAP and then liquidate our positions at the year end. We perform the same exercise at the end of PEAP 2, 3, and 4. At the end of each PEAP, we form four portfolios based on the quartiles of the distribution of the variances. This strategy captures returns for three (two and one) quarters because positions created after PEAP 1 (2 and 3) have only three (2 and 1) quarters remaining before the year end. For the portfolios constructed at the end of PEAP 4, we hold the portfolio till the end of the following year (for four quarters) and liquidate our position at the end of the following year. Since the objective is to examine the economic significance of forecast improvement based on the variances, only the *ex ante* measures are reported. First, we classify firms into good news and bad news based on our *ex ante* definitions (C&D) and rank them by variances from high to low within each group. This way we create four portfolios: good news & high variance, good news & low variance, bad news & high variance and bad news & low variance.

After the formation of portfolios, we implement three trading strategies. For the first trading strategy, we buy good news & low variance stocks and hold them till the year-end and calculate the average raw returns. We also calculate the average raw returns for a good news & high variance portfolio. The difference in raw returns between these two portfolios represents our measure of arbitrage return for this trading strategy. For the second trading strategy, we buy and hold the firms with bad news & low variance, calculate the raw return at the end of the year, and subtract from this the returns on the portfolio with bad news & high variance. Finally, the third trading strategy

974

creates the arbitrage return measure by subtracting the buy and hold returns of the bad news & high variance portfolio from those of the good news & low variance portfolio. We use raw returns because the market return factor that would be common for all portfolios would cancel out in our arbitrage returns measure.

Table 6 presents the results of the three trading strategies for the two different ex ante definitions of good news and bad news for the four portfolio holding periods. For each trading strategy, there are positive abnormal returns based on the variance as well as the nature of the news. The difference in the low and high variance portfolios with *good* news is 0.0583 (0.0272, 0.0063 and 0.0517) for definition C and 0.055 (0.025, 0.0133, and 0.0686) for definition D for the four holding periods. Similarly the difference in the low and high variance portfolios with *bad* news is -0.0068 (-0.005, 0.0534 and 0.14) for definition C and 0.139 (-0.0437, 0.0594, and 0.13) for definition D for the four holding periods. Seven (one) positive differences out of the total eight are significant at conventional levels of significance (0.05 or better) for the good (bad) news firms. None of the negative differences are significant. Thus, variance seems to play a more significant role for firms with good news than those with bad news. We conclude from these results that, in general, high variance portfolios have lower returns than low variance portfolios after controlling for the nature of the expected news.

As per Hypothesis 4, the third trading strategy (good news & low variance versus bad news & high variance) should generate highest returns. Under definition C, this strategy provides highest returns for three out of the 4 holding periods. The only exception is the full one year return, where other

975

confounding factors could have diluted the effect. However, under definition D, we do not find support for the argument that good news & low variance and bad news & high variance should generate highest returns. The highest returns are for the good news firms with low and high variance. Overall, our results are consistent with the hypothesis that abnormal returns can be obtained when the variance of analysts' forecasts are conditional upon the good-news and bad-news scenarios. These results also provide insights into the findings of Diether et al. (2002) that abnormal returns based on variance are driven mostly by the firms expecting good news.

5. DISCUSSION AND CONCLUDING REMARKS

Consistent with the notion that significantly increased informational uncertainties mark a bad news environment compared with a good news environment, we find a greater variance in analysts' forecasts in all bad news environments. Although this finding is consistent with the notion of managers' differential incentives to select information release timing, alternative explanations do not enable us to arrive at such a conclusion. Instead, our evidence indicates that such strategic behavior, if any, affects the informational uncertainty of the forecast environment, as well as the forecasts issued during at least the first three quarters of the fiscal year. To the extent our results are driven by management's tendency to withhold bad news, our results indicate that even if there were alternative information sources, these alternative sources do not seem to act as credible substitutes for the firm management during this period. We also provide some evidence that differential distributional properties of the forecasts, specifically the conditional

variance, under good-news and bad-news environments have incremental predictive power for predicting earnings levels.

Our evidence is also consistent with the idea that the distributions of analysts' earnings forecasts are significantly different in good news or a bad news environment. This finding has some implication for any study that assumes analysts' forecast variances represent random variables from a single population. Our evidence indicates a need to consider forecast variances conditioned on good news and bad news. The existence of arbitrage return for portfolios constructed with analyst forecast variance is consistent with the predictive power of forecast variances of annual earnings. We refrain from making any conclusions regarding market efficiency because these returns do not consider factors such as transaction costs. Future research is needed in these areas.

[1] For inclusion in the sample, the firm must have analysts' forecast variance data for *all* four PEAPs of the year over a minimum of seven years during the period, 1996-2006. Analysts forecast variance is computed for firms with a minimum of four distinct analysts' forecasts in any pre-earnings announcement period (PEAP).

Table 2

Analyst forecast variance for the two *ex post* and two *ex ante* definitions of good-news and bad-news, by year and PEAP. *Ex post* good news is defined as meeting or exceeding previous years' earnings (A), or as reporting profits (B). *Ex ante* good news is when the mean of analyst earnings forecasts exceeds previous years' earnings (C) or the mean of analysts' earnings forecasts exceeds zero (D). Bad news is defined as the absence of good news.

Year	Good-News Definitions (ex post)								Good-News Definitions (ex ante)							
	Exceeding Previous Years' Earning (A)				Reporting Profits (B)				Expected to Exceed Previous Years' Earning (C)				Expected to Report Profits (D)			
	Bad-News	Good-News	Bad News-Good News		Bad-News	Good-News	Bad News-Good News		Bad-News	Good-News	Bad News-Good News		Bad-News	Good-News	Bad News-Good News	
1996	0.09	0.06	0.03	***	0.17	0.09	0.08	***	0.1	0.06	0.04	***	0.16	0.09	0.08	***

PUBLIC DISCLOSURE, PRIVATE INFORMATION, AND INVESTMENT EFFICIENCY

Yoshikazu Ishinagi, Nagoya University of Commerce and Business
Atsushi Shiiba, Osaka University,
Hiroji Takao, Osaka University

Abstract

This paper investigates how and when the quality of accounting information improves firm investment efficiency. In particular, we focus on the role of public disclosure in forming more efficient security prices and thereby improving firm investment. Using a stock market model that incorporates managerial investment decisions, we show in general that higher quality accounting information generally improves investment efficiency by reducing information asymmetries, and this is consistent with recent empirical findings.

Key Words: public disclosure, private information, investment efficiency, information asymmetry, market liquidity

1. Introduction

This paper investigates how and when the quality of accounting information improves firm investment efficiency using a stock market model that incorporates managerial investment decisions. In particular, we focus on the role of public disclosure in forming more efficient security prices and thereby improving firm investment. Recent empirical research suggests that higher quality financial reporting improves capital investment efficiency by reducing information asymmetries. For example, Biddle and Hilary (2006) examine how accounting quality relates to capital investment efficiency, and empirically find that higher quality accounting enhances investment efficiency by reducing information asymmetry between managers and outside suppliers of capital. Similarly, Biddle et al. (2008) find that higher quality financial reporting enhances investment efficiency. In particular, they find a negative

association between financial reporting quality and investment in firms operating in settings prone to overinvestment. However, financial reporting quality and investment are positively associated for firms operating in settings prone to underinvestment. These findings suggest that accounting information quality improves the economic performance of firms.[140]

However, high-quality public disclosure may not improve investment efficiency. For example, stock prices may not be an adequate indicator upon which we could base compensation to reward managerial effort. Recent corporate crises indicate that stock-based compensation distorts manager's effort toward short-term outcomes. See, for instance, Bolton et al. (2006) for a recent analytical model based on stock price efficiency.[141] In sum, we cannot claim that public disclosure always improves stock price efficiency and thereby firm investment efficiency. In this paper, we attempt to identify the conditions where the quality of accounting information improves managerial investment decision making.

Our model extends the single-signal framework in Kyle (1985) by introducing a second public signal that the firm must disclose. In this capital market setting, we examine firm investment efficiency as a key determinant of economic productivity. The work most related to the present analysis is Fishman and Hagerty (1989), as they also model managerial decision making on investments using an extension of the model in Kyle (1985). However, unlike Fishman and Hagerty (1989), we explicitly model public information along with private information, and examine a setting in which both a market maker and informed traders know this information. We also

---

[140] Several recent empirical studies concern the relation between investment efficiency and earnings management. See, for instance, McNichols and Stubben (2008), Kedia and Philippon (2009) and Durnev and Mangen (2009). However, we do not consider earnings management here.

[141] There may be another reason why high-quality public disclosure may not improve the economic performance of firms. Public information sometimes communicates a firm's proprietary information to competitors. In fact, some studies suggest an association between competition and voluntary disclosure. See, for example, Guo et al. (2004) and Jin (2005). In considering this effect, we could argue that managers change the level of investment when the precision of public information changes, and this could decrease firm profits.

assume manager is risk averse, unlike Fishman and Hagerty (1989) who assume that she is risk neutral. Our findings suggest that higher quality accounting information generally improves investment efficiency by reducing information asymmetries. This is consistent with the empirical evidence in Biddle and Hilary (2006) and Biddle et al. (2008).

The remainder of the paper is organized as follows. Section 2 constructs the basic model. In Section 3, we explicitly characterize the stock price based on publicly available information and the equilibrium level of investment. Section 4 concludes.

2. Model

We assume that a manager and three kinds of traders in a capital market populate the economy. There are three periods. In the first period, the manager makes decisions on how much money to invest in a project. In the second period, public and private information about the liquidated value of the project is released and trading takes place. Finally, in the third period, the project is realized and the firm is liquidated. We assume that there is no time discount across the three periods; that is, the interest rate is zero.

The investment has a normally distributed random return of $\tilde{v} \sim N(\bar{v}, \sigma^2)$. The manager knows these distribution parameters and chooses to invest α dollars in the project. That is, the value of the firm is $\tilde{V} = \alpha\tilde{v}$ and is normally distributed with mean $\alpha\bar{v}$ and variance $\alpha^2\sigma^2$. The manager is assumed to be risk averse with utility $U(Welfare) = -Exp(-r * Welfare)$. We also assume that the manager already has a contract that is a function of the stock price P. Alternatively, the manager sells her shares in the market at P and engages in consumption. The manager then makes an investment decision to maximize her expected utility; that is, $\max_\alpha E[U(P)]$.

In the next period, the firm's stock price is determined in the market. The market model we use is an extension of Kyle (1985). Here, the stock market comprises a single risk-neutral informed trader, uninformed traders and a competitive risk-neutral market maker. The manager releases public information concerning the future returns of the investment and trading takes place.

The informed trader observes the public earnings information and privately observes another signal, and then submits orders x for the firm's stock given this information. Uninformed traders can observe none of this kind of information and can submit random orders of $\tilde{u} = u$ where $\tilde{u} \sim N(0, \sigma_u^2)$. That is, the informed trader's trading is exogenous. The market maker observes the public information and additionally observes total orders of $Y = x + u$. The market maker sets price P such that he expects to earn a zero profit given the total orders and public earnings information. The presence of uninformed traders makes it impossible for the market maker to infer exactly the informed trader's private information.

Private information $\tilde{s}$, which only the informed trader will receive, is normally distributed with zero mean and unit variance; that is, $\tilde{s} \sim N(0,1)$. The public earnings information $\tilde{e}$, which can be observed by both the informed trader and the market maker, is also normally distributed with zero mean and unit variance; that is, $\tilde{e} \sim N(0,1)$. The random investment return $\tilde{v}$ and signals $\tilde{s}$ and $\tilde{e}$ are correlated, and are denoted by ρ_{vs}, ρ_{ve} and ρ_{se}, respectively. Without loss of generality, we assume that $0 \leq \rho_{vs}, \rho_{ve}, \rho_{se} < 1$. That is, signals $\tilde{s}$ and $\tilde{e}$ are positively correlated with investment return (otherwise, the opposing signal can be used instead of the original signal); therefore, these signals are also positively correlated with each other.

In equilibrium, the manager chooses the investment level α by anticipating the effects of her decision on the firm's stock price P. The price is determined in the market such that the informed trader's anticipation of the price and the actual price are equal. The following provides a definition of the equilibrium of this model.

Definition

We define equilibrium in this model as a pair (α, x, P) such that the following three conditions hold:

1. The manager invests to maximize her expected utility,

$$\alpha = \operatorname*{argmax}_{\alpha} E[U(P)]$$

.

2. The informed trader makes orders x subject to for any alternative trading strategy x' and for any v,

$$E[(\alpha\tilde{v} - P)x|s,e] \geq E[(\alpha\tilde{v} - P)x'|s,e]$$

.

3. The price is determined such that the market maker receives zero expected profits,

$$P(Y,e) = E[\tilde{V} = \alpha\tilde{v}|Y, e]$$

.

3. Equilibrium analysis

3.1 Equilibrium in the model

We focus on the optimal investment decision by the manager. The manager makes her investment decision by anticipating the effects of her investment decision on the stock price of the firm. The market maker, observing both the total order flow $Y = u + x$ and the public earnings information e provided by the manager, then sets the stock price. Using backward induction, we first find the equilibrium stock price P and the optimal order amount x, conditional on the manager's investment. In

deriving the equilibrium in this model, we focus on the linear equilibrium. It is well known that this equilibrium concept is the same as Kyle (1985). We then solve for the optimal investment decision by the manager.

The following lemma provides the characterization of the equilibrium stock price and the demand of informed traders.

Lemma 1. The unique equilibrium is given by:

$x = \beta_1 s + \beta_2 e$, and

$P = \alpha \bar{v} + \lambda_1 Y + \lambda_2 e = \alpha \bar{v} + \lambda_1 (u + x) + \lambda_2 e$,

where

$$\beta_1 = \frac{\sigma_u}{\sqrt{1 - \rho_{se}^2}} \ ,$$

$$\beta_2 = -\frac{\sigma_u \rho_{se}}{\sqrt{1 - \rho_{se}^2}} \ ,$$

$$\lambda_1 = \frac{\alpha \sigma \left(\rho_{Vs} - \rho_{Ve} \rho_{se} \right)}{2 \sigma_u \sqrt{1 - \rho_{se}^2}} \quad \text{and}$$

$$\lambda_2 = \alpha \sigma \rho_{Ve} \ .$$

Proof. See Appendix A.

We see that the informed trader places different weights on the private and public earnings information in making a decision on his demand. Further, we also see that these two weights are in the opposite direction. The relative weight is $\dfrac{\beta_1}{\beta_2} = -\rho_{se}$. Therefore, the informed trader is attaching relatively greater importance to his private signal than the public earnings signal as the correlation between the two signals becomes higher.

Note that $\lambda_1 > 0$ because the second-order profit maximization condition for the informed trader requires $-2\lambda_1 < 0$. In this model, λ_1 is an increasing function of the amount invested by the manager α and the volatility of the investment return (or firm profitability) σ^2, and a decreasing function of the variance of the uninformed traders' order flows σ_u^2. It could be viewed λ_2 as a value-relevant measure of the public earnings information. We see in this model that λ_2 is increasing in the manager's level of investment α, the volatility of the investment return σ and the correlation between the value of the firm and the public earnings information ρ_{Ve}.

3.2. Manager's investment

Next, let us consider the manager's investment policy for maximizing her expected utility with a negative exponent. To do this, we need to solve the following problem,

$$\max_{\alpha} E[U(P)]$$

subject to $P = \alpha\bar{v} + \lambda_1 Y + \lambda_2 e$.

The constraint is necessary to reflect the situation in which the manager takes into consideration how her investment will affect the stock price when the manager makes an investment decision.

3.2.1 Perfect information case (first-best scenario)

To start with, we consider the perfect information case in which the market maker sets the stock price equating to the realized value of the firm; that is, where $P = \alpha v$. We can regard this as the benchmark for evaluating the manager's choice of investment in the model.

Lemma 2. In the perfect information case in which means that $P = \alpha v$, the manager's

optimal investment is given by $\alpha_{FB} = \dfrac{\bar{v}}{r\sigma^2}$.

Proof. See Appendix A.

This obviously suggests that the manager's investment increases with the mean of the investment return and decreases with both the variance of the investment return and the magnitude of the manager's risk aversion.

3.2.2 Imperfect information case (second-best scenario)

Now, we consider the imperfect information case in which the stock price is set by the market maker who only observes the public earnings information $\tilde{e}$ and the total order $\tilde{Y} = \tilde{u} + \tilde{x}$ as a two-signal version of the model in Kyle (1985). In other words, the stock price is informationally imperfect in the sense that the market maker sets the stock price without knowing the informed trader's private information $\tilde{s}$ and the value of the firm $\alpha\tilde{v}$, as well as without separating the informed trader's order flow $\tilde{x}$ from the uninformed trader's order flow $\tilde{u}$.

More specifically, the manager faces the following problem when she makes her choice of the investment level:

$$\max_{\alpha}\left\{E(P) - \frac{r}{2}Var(P)\right\}$$

subject to $P = \alpha\bar{v} + \lambda_1 Y + \lambda_2 e$.

The following proposition provides some characterizations of the optimal investment policy undertaken by the manager.

Proposition 1

(a) In the imperfect information case, the manager's investment policy is given by:

$$\alpha_{SB} = \frac{\bar{v}}{r\sigma^2 \left[\dfrac{(\rho_{Vs} - \rho_{Ve}\rho_{se})^2}{2(1-\rho_{se}^2)} + \rho_{Ve}^2 \right]}.$$ (1)

(b) The manager overinvests in the sense that $\alpha_{SB} > \alpha_{FB}$ if

$(\rho_{Vs} - \rho_{Ve}\rho_{se})^2 < 2(1-\rho_{Ve}^2)(1-\rho_{se}^2)$ and underinvests in the sense that $\alpha_{SB} < \alpha_{FB}$ if

$(\rho_{Vs} - \rho_{Ve}\rho_{se})^2 > 2(1-\rho_{Ve}^2)(1-\rho_{se}^2)$. If $(\rho_{Vs} - \rho_{Ve}\rho_{se})^2 = 2(1-\rho_{Ve}^2)(1-\rho_{se}^2)$, the manager invests

optimally in the sense that α_{SB} is equal to α_{FB}.

Proof. See Appendix A.

   The main issue of interest in this paper is the relationship between information

quality and corporate investment efficiency. In other words, would information quality,

particularly the quality of public earnings information, improve corporate investment

efficiency? To investigate this problem, let us first observe how the optimal

investment level in the imperfect information case α_{SB} depends on the correlation

among the value of the firm $\alpha\tilde{v}$, the public earnings signal $\tilde{e}$ and the private signal $\tilde{s}$.

The following proposition provides some comparative static results of the managers'

investment policy in equilibrium. Here, it is natural that the quality of the information is

described by the correlation coefficient between the value of the firm and each signal.

Proposition 2

(a) If the private signal $\tilde{s}$ and public earnings signal $\tilde{e}$ are independent ($\rho_{se}=0$,

   hereafter "the independent case"), the optimal investment level α_{SB} decreases as

   the quality of the private signal ρ_{Vs} and/or the public earnings signal ρ_{Ve} become

   better (higher). Further, the effect of ρ_{Ve} on the reduction in investment is larger

   relative to ρ_{Vs} (the magnitude of the effect of ρ_{Ve} is double).

(b) The optimal investment level decreases as the quality of the private signal becomes higher.

(c) The optimal investment level decreases when the quality of public earnings information is high ($\rho_{Ve} \geq \frac{1}{2}$).

(d) The optimal investment level increases with a higher correlation coefficient between the private signal and the public earnings signal if $(\rho_{Ve} - \rho_{Vs}\rho_{se}) > 0$ and decreases with a higher correlation coefficient between the private signal and the public earnings signal if $(\rho_{Ve} - \rho_{Vs}\rho_{se}) < 0$. If $(\rho_{Ve} - \rho_{Vs}\rho_{se}) = 0$, the optimal investment level is unchanged.

Proof. See Appendix A.

3.2.3 The quality of the signals and investment efficiency

It is now possible to consider how the information quality affects corporate investment efficiency. In dealing with this problem, we note the quality of the public earnings information ρ_{Ve}, as ρ_{Ve} captures an aspect of the characterization of the accounting information.

We define the following threshold function $Z(\rho_{Ve})$ based on Proposition 1(b) to specifically identify the overinvestment and the underinvestment region respectively in terms of ρ_{Ve} :

$$Z(\rho_{Ve}) \equiv 2(1 - \rho_{se}^2)(1 - \rho_{Ve}^2) - (\rho_{Vs} - \rho_{se}\rho_{Ve})^2 . \tag{2}$$

Clearly, $Z(\rho_{Ve}) > (<)0$ represents the manager's overinvestment (underinvestment) in the imperfect information case relative to the first-best investment level in the perfect information case, and $Z(\rho_{Ve}) = 0$ means that the manager's investment level α_{SB} is equivalent to the first-best case α_{FB}. If we assume the public earnings signal

$\tilde{e}$ fully reflects the value of the firm in the sense that $\rho_{Ve} = 1$, we provide the following proposition.

Proposition 3.

The quality of public earnings information would enhance the manager's investment efficiency in the sense that the manager undertakes the first-best investment if the public earnings signal was informationally perfect ($\rho_{Ve} = 1$).

Proof. $\rho_{Vs} = \rho_{se}$ in the case of $\rho_{Ve} = 1$. Inserting into eq. (2), $Z(\rho_{Ve}) = 0$.

4. Concluding Remarks

This paper investigates how the quality of accounting information improves a firm's investment efficiency using a stock market model that incorporates the manager's investment decisions. In particular, we focus on the role of public disclosure in forming more efficient security prices and thereby improving firm investment. Recent empirical research suggests that higher quality financial reporting Our results indicate that higher quality accounting information generally improves investment efficiency by reducing information asymmetries, and this is consistent with the empirical findings in Biddle and Hilary (2006) and Biddle et al. (2008).

Appendix A

Proof of Lemma 1

Given any vector of normal random variables X_1 and any vector of normal random variables X_2,

$$\begin{pmatrix} X_1 \\ X_2 \end{pmatrix} \sim N(\mu, \Sigma), \text{ where } \mu = \begin{pmatrix} \mu_1 \\ \mu_2 \end{pmatrix} \text{ and } \Sigma = \begin{pmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{pmatrix},$$

then,

$$E[X_1|X_2] = \mu_1 + \Sigma_{12}\Sigma_{22}^{-1}(X_2 - \mu_2), \text{ and}$$

$$V[X_1|X_2] = \Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21}.$$

Proof of Lemma 2

The manager faces the following problem in maximizing her utility in the perfect information case,

$$\max_{\alpha}\left\{E(P) - \frac{r}{2}Var(P)\right\}$$

subject to $P = E[\alpha\tilde{v}]$.

Taking the first-order condition with respect to α and equating it to 0, we have

$$\bar{v} - r\sigma^2\alpha = 0 \text{ and, therefore, } \alpha_{FB} = \frac{\bar{v}}{r\sigma^2}.$$

Proof of Proposition 1(a)

From Lemma 1, $E(P) = \alpha\bar{v}$ and $Var(P) = \alpha^2\sigma^2\left[\frac{(\rho_{Vs} - \rho_{Ve}\rho_{se})^2}{2(1-\rho_{se}^2)} + \rho_{Ve}^2\right]$. Taking the first-order condition with respect to α and equating it to 0, we then have α_{SB}, as in Proposition 1(a).

Proof of Proposition 1(b)

It is obvious from a comparison of the amounts invested in the imperfect information case α_{SB} and the perfect information case α_{FB}, specifically from comparing $\frac{(\rho_{Vs} - \rho_{Ve}\rho_{se})^2}{2(1-\rho_{se}^2)} + \rho_{Ve}^2$ in the former with 1 in the latter.

Proof of Proposition 2 (a)

In the independent case, $\rho_{se} = 0$, eq. (1) can be written as $\alpha_{SB} = \dfrac{\bar{v}}{r\sigma^2 \left[\dfrac{\rho_{Vs}^2}{2} + \rho_{Ve}^2 \right]}$.

The proof is obvious from this expression.

Proof of Proposition 2 (b)

From eq.(1), $\dfrac{\partial \alpha_{SB}}{\partial \rho_{Vs}} = - \dfrac{1}{r\sigma^2 \left(\dfrac{(\rho_{Vs} - \rho_{Ve}\rho_{se})}{2(1 - \rho_{se}^2)} + \rho_{Ve}^2 \right)^2} \, \bar{v} \, \dfrac{(\rho_{Vs} - \rho_{Ve}\rho_{se})}{(1 - \rho_{se}^2)}$. In addition,

$\lambda_1 > 0$ due to the second-order profit maximization condition for the informed trader.

Therefore, we have $(\rho_{Vs} - \rho_{Ve}\rho_{se}) > 0$, and thus $\dfrac{\partial \alpha_{SB}}{\partial \rho_{Vs}} < 0$.

Proof of Proposition 2 (c)

$\dfrac{\partial \alpha_{SB}}{\partial \rho_{Ve}} = - \dfrac{1}{r\sigma^2 \left(\dfrac{(\rho_{Vs} - \rho_{Ve}\rho_{se})}{2(1 - \rho_{se}^2)} + \rho_{Ve}^2 \right)^2} \, \bar{v} \, \dfrac{2\rho_{Ve} - \rho_{se}(\rho_{Vs} - \rho_{Ve}\rho_{se})}{(1 - \rho_{se}^2)}$. $(\rho_{Vs} - \rho_{Ve}\rho_{se}) > 0$ from the

second-order profit maximization condition for the informed trader. Also, $1 > \rho_{se} \geq 0$,

$1 > \rho_{Ve} \geq 0$ and $1 > \rho_{Vs} \geq 0$ by the definition and assumptions. Therefore,

$1 > (\rho_{Vs} - \rho_{Ve}\rho_{se}) > 0$, then $1 > \rho_{se}(\rho_{Vs} - \rho_{Ve}\rho_{se}) \geq 0$. If $\rho_{Ve} \geq \dfrac{1}{2}$, it is at least true that

$2\rho_{Ve} - \rho_{se}(\rho_{Vs} - \rho_{Ve}\rho_{se}) \geq 0$.

Proof of Proposition 2 (d)

1000

Proposition 2 (d) follows immediately from differentiation of eq. (1),

$$\frac{\partial \alpha_{SB}}{\partial \rho_{se}} = \frac{1}{r\sigma^2 \left(\frac{(\rho_{Vs} - \rho_{Ve}\rho_{se})}{2(1-\rho_{se}^2)} + \rho_{Ve}^2\right)^2} 2\bar{v} \frac{(\rho_{Ve} - \rho_{Vs}\rho_{se})(\rho_{Vs} - \rho_{Ve}\rho_{se})}{(1-\rho_{se}^2)}$$

, and $(\rho_{Vs} - \rho_{Ve}\rho_{se}) > 0$.

PERFORMANCE EVALUATION OF TURKISH PENSION MUTUAL FUNDS USING MORNINGSTAR-STAR RATING SYSTEM

Prof. Dr. Sudi APAK*

Dr. Kamer Hagop TAŞCIYAN**

ABSTRACT

The Morningstar-star rating system has been used commonly in both academic and practitioner circles as having the most effective rating tool in the mutual fund industry. A system created by Morningstar company which rates mutual funds based on their risk-adjusted performance over various periods from one star (the worst) to five star (the best).

In this study we use Morningstar-star rating system to analyse weighted performance of Turkish pension mutual funds during the period January 2004-December 2008. In this context pension mutual funds are grouped into five and weighted performance results are rated.

***Key Words**: Pension mutual funds, performance, Morningstar-star rating system.*

INTRODUCTION

Funded pension schemes are becoming a key point for modern economies and economic policy. Increasing demographic pressure combine with the need of reforming the existing ineffective and politically vulnerable systems bring about the current trends to privatese the modern welfare state and to use capital market-based solutions in the old age provision.[142]

A number of countries have implemented or proposed fundemental reforms of their pension systems including Latin American countries such as Chile (1981), Peru (1993), Argentina (1994), Colombia (1994), Uruguay (1995), Bolivia (1997), Mexico (1998), El Salvador (1998) and European countries such as United Kingdom (1988), Czech Republic (1998), Hungary (1998) and Poland (1999). These reforms emphasise the role of individual, privately managed defined-contributions accounts, where the value of the pension benefit will depend on accumulated contributions and investment returns.[143]

Turkey also started pension reform process in 1999. Turkey's 1999 reform implemented a two-pillar system, maintaining public social security institutions with some changes (the first pillar) and introducing private pension schemes (the second pillar).[144] So the Individual Retirement Law in Turkey has been legislated in parliament and published in the Official Gazette on May, 7th 2001. The law was enacted after 6 months following the publishing date and Turkish Individual Pension System commenced on October 27, 2003. According the law no. 4632 on Individual Pension Savings and Investment System, which is complementary to the state social security system and only the licensed pension companies are entitled to sell personel private pension products and collect personel pension contributions is called pension mutual funds, which are mutual funds founded by the pension companies exclusively for the investment of pension monies.

In this study Morningstar-star rating system is used for performance rating of Turkish pension mutual funds which was introduced in 2003. Pension mutual funds from which to choose and investors need a shortcut to aid in their decision making. In the absence of a better alternative, households often focus on absolute returns because this measure is a concept that they readily grasp. This focus, however, leads them to ignore such other important factors as risk and expenses. The Morningstar ratings have the potential to improve household investment decisions by providing a signal of fund quality that is as easy to understand as absolute returns but better grounded in investment theory. That is, the star

ratings make the results of sophisticated analysis accessible to the public. For professional investors, although they realize they need to look at relative risk-adjusted returns (adjusted for expenses), personally performing this calculation on each and every portfolio is costly. Morningstar thus provides a valuable service for them. Professional investors can use the star ratings as Morningstar intended- as a starting point in building a portfolio that matches specific goals and tolerances for risk.[145]

So we organize the rest of the paper as follows, Section 1 defines the Morningstar-star rating system, Section 2 describes Morningstar-star rating system calculation procedures, Section 3 explains study framewok, and Section 4 concludes Morningstar weighted performance and rating results of Turkish pension mutual funds.

1. MORNINGSTAR STAR-RATING SYSTEM

With the tremendous growth of privately managed retirement accounts and the more than 10,000 now available to investors in US.[146] Numerous magazines and newspapers, like Fortune, Kplingers, Money, USA Today and the Wall Street Journal, all now provide comprehensive fund ratings/rankings in order to help investors their way through the numerous funds that are advertised each day in leading publications.

Despite the entry of these popular publications into the mutual fund rating business, the most well known mutual fund rating system is currently provided by Morningstar Inc. Started in the mid-1980s, the company has grown largely as a result of the sucess of its now famous 5-star rating system. Similar to the ratings given to hotels, movies, or restaurants, Morningstar rates mutual funds on a scale of 1 to 5 stars, where 1 star is the worst rating and 5 star is the best. Because of the ratings system's similarity to the way we rate so many other products, and its high regard within the industry, the star rating system has become part of the accepted lexicon in mutual funds.[147]

The Morningstar-star rating system has become so popular that a fund receiving a high star rating is often deemed by the public to have something like ''a Good Housekeeping seal of approval''. In fact some financial planners reported that investors require them invest only in funds with four-or-five star ratings. One study found that as much as 90 percent of new money invested in stock funds in 1995 went to funds with four-star or five-star ratings.[148] And a recent study by Financial Research Corporation of Boston, which was reported in the Wall Street Journal found that in 1999, funds with four or five stars received inflows of $223.6 billion whereas funds with three or fewer stars had outflows of $132 billion.[149] Moreover, the heavy use of Morningstar ratings in mutual fund advertising (in some cases, the only mention of return performance in the mutual fund advertisement is the Morningstar rating) suggests that mutual fund firms believe that investors care about Morningstar ratings.[150] For example, in 2001-2004, companies such as American Century, Dreyfus, Fidelity, Franklin Resources, Northern Funds, and Strong Funds all run advertisements that emphasized star ratings rather than their own return histories.[151]

2. MORNINGSTAR STAR-RATING SYSTEM CALCULATION PROCEDURES

To calculate its ratings, Morningstar first classifies funds into one of four categories: domestic equity, foreign equity, municipal bond, and taxable bond.[152] The ratings are then

[151] MOREY Matthew R., GOTTESMAN Aron, Morningstar Mutual Fund Ratings Redux, The Journal of Invesment Consulting, Vol.8, No.1, Summer 2006, p.25

[152] Morningstar-star rating grouped mutual funds into four categories: domestic equity, foreign equity, municipal

based upon an agregation of the three-, five-, and 10-year risk-adjusted return for funds with 10 year risk-adjusted return for funds with 10 years or more of return history, three- and five-year risk-adjusted returns for funds with five to less than 10 years of return data, and three-year risk-adjusted returns for funds with five to less than five years of return data. To calculate the risk-adjusted return for the fund by adjusting returns for expenses and other costs automatically taken out of the fund, and then by adjusting for front-end and deferred loads. Next, Morningstar calculates a "Morningstar return" in which the expense-and load-adjusted excess is return divided by the higher of two variables: the excess average return of the fund category or the average 90-day T-bill rate; [153]

$$\frac{(\text{Expense- and Load-Adjusted Return on the Fund} - \text{T-Bill})}{\max[(\text{Average Category Return} - \text{T-Bill}), \text{T-Bill}]}$$

Morningstar then calculates a "Morningstar risk" measure, which is calculated differently from traditional risk measures, such as beta and standard deviation that both see greater-than and less-than-expected returns as added volatility. Morningstar believes that most investors' greatest fear is losing money, which Morningstar defines as underperforming the risk-free rate of return an investor can earn from the 90-day Treasury bill. Hence, their risk measure only focuses on downside risk.[154] To calculate risk, Morningstar plots monthly returns in relation to T-bill returns, adds up the amounts by which the fund trails the T-bill return each month, and then divides that total by the time horizon's total number of months. This number, the average monthly underperformance statistic, is then compared with those of other funds in the same broad investment category to assign the risk scores. The resultant Morningstar risk score expresses how risky the fund is relative to the average fund in its category.

To calculate a fund's summary star rating, Morningstar calculates the three-, five-, and 10-year Morningstar return and risk. For each time horizon, the Morningstar calculates its raw rating by subtracting the Morningstar risk score from the Morningstar return score. Then the three numbers (one for each time horizon) are then given subjective weights. The three-year number receives a 20% weighting, the five-year a 30% weighting, and the 10-year a 50% weighting. In the case of young funds (funds with three to less than five years of return data), the three-year number receives a 100% weighting; in the case of middle-aged funds (funds with five to less than 10 years of return data), the three-year number receives a 40% weighting and the five-year number receives a 60% weighting. With these weights, Morningstar calculates the weighted average of the numbers. (See Figure 1) The resulting number is then plotted along a bell curve to determine the fund's star rating. If the fund scores in the top 10% of its broad investment category, it receives a rating of five stars; if the fund falls in the next 22.5%, it receives four stars; if it falls in the middle 35%, it receives three stars; if it lies in the next 22.5%, the fund receives two stars, and if it is in the bottom 10%, it receives one star.[155]

bond and taxable bond. But Turkish pension mutual funds differ from any aspects (asset classes, investment strategies, size etc.) from US mutual funds. Therefore in the study pension mutual funds category numbers are enlarged.

[154] Focusing only on downside risk is neither unique to Morningstar nor new; it was explored by Markowitz (1959) and incorporated into an asset-pricing model by Bawa and Lindenberg (1977).

[155] BLAKE R. Christopher, MOREY Matthew R., a.g.e., p.458

3. STUDY FRAMEWORK

According to the PMC (Pension Monitoring Center) and CMB (Capital Market Board) Turkish pension mutual funds are grouped into five categories. Therefore in the study the pension mutual funds are **grouped into five categories** according to the asset types as follows;

1) Flexible-Balanced Funds: Pension mutual funds, asset allocation of which are not pre specified, are determined by a portfolio manager in accordance with the market conditions and main limits laid down at the relevant regulation. This funds portfolio mainly consists of Gov't Bonds and Bills and can be supported by trading shares listed at ISE (Istanbul Stock Exchange), especially during the uptrend market periods.

2) Stock Funds: Pension mutual funds include minimum 80% of stocks in their portfolios, the return trend of funds are highly corellated with ISE .

3) Gov't Bonds and Bills Funds: Pension mutual funds include minimum 80% of Gov't Bonds and Bills in their portfolios.

4) International-Currency Indexed Funds: Pension mutual funds which carry minimum 80% of foreign instruments, with the returns of Euro and USD.

5) Liquid Funds: Pension mutual funds portfolio consists of capital market instruments of high liquidity with a maximum maturity of 180 days, and the upper limit of weighted average maturity of the portfolio is 45 days.

So in the study the number of 60 funds which are 13 Flexible-Balanced Funds, 8 Stock Funds, 11 Gov't Bonds and Bills Funds, 15 International-Currency Indexed Funds and 13 Liquid Funds are rated using Morningstar-star rating system during January 2004-December 2008 time period.[156]

In order to understand the main aspects of the study we explain return and risk variables calculation as follows;

a) Return Data: Firstly pension mutual funds monthly return (%) used in the study. The return of the pension fund calculated as below;[157]

$$r_p = \frac{V_t - V_{t-1}}{V_{t-1}}$$

r_p : Pension mutual funds return

V_t : Pension fund unit price at t month

V_{t-1} : Pension fund unit price at preceding month

Secondly we use 91 day Trasury bill rate[158] to calculate Morningstar return. As we know to calculate the risk-adjusted return for the fund by adjusting returns for expenses and other costs automatically taken out of the fund, and then by adjusting for front-end and deferred loads. Next, Morningstar calculates a ''Morningstar return'' in which the expense-and load-adjusted excess is return divided by the higher of two variables.[159]

b) Risk Data: Standard deviation is sometimes criticized as being an inadequate measure of risk because investors do not dislike variability per se. Rather, they dislike losses but are quite happy to receive unexpected gains. One way to meet this objection is to calculate a measure of downside variability, which takes account of losses but not of gains. For example, we could calculate a measure of average monthly underperformance as follows:[160] 1) Count the number of months when the fund lost money or underperformed Treasury bills, that is, when excess returns were negative. 2) Sum these negative excess returns. 3) Divide the sum by the total number of months in the measurement period.

---

[156] In the analyze period some pension firms are merged or bought by the local and international insurance firms. Therefore changed pension firms/funds name updated according to CMB (Capital Market Board) of Turkey.

[157] CPM (Capital Market Board), http://www.spk.gov.tr/apps/aylıkbulten/index.aspx

[158] 91 day T-bill rate of return (%) obtained from ISE (Istanbul Stock Exchange) Bonds and Bills Market Data, http://www.imkb.gov.tr/veri.htm

[159] In the study the average T-bill rate is bigger variable than the excess average return of the category. So we prefer to use the average 91-day T-bill rate.

[160] SIMONS Katerina, ''Risk-Adjusted Performance of Mutual Funds'', New England Economic Review, September/October 1998, p.36

Morningstar use downside risk in Morningstar risk calculation and this final risk score expresses how risky the fund is relative to the average fund in its category. While downside risk may be a better reflection of investors' attitudes towards risk, empirical evidence suggests that the distinction between downside risk and the standard deviation is not as important as it seems because the two measures are highly correlated. Sharpe[161] (1997) analyzed monthly standard deviations of excess returns and average monthly underperformance in a sample of 1,286 diversified equity funds in the three-year period between 1994 and 1996. He found a close relationship between these two measures, with a correlation coefficient of 0.932. Such a close correlation is not surprising, since monthly stock returns generally follow a symmetrical bell-shaped distribution. Therefore, stocks with larger downside deviations will also have larger standard deviations.

4. PENSION MUTUAL FUNDS WEIGHTED PERFORMANCE AND STAR-RATING RESULTS

The investment process of pension mutual funds is strategically important as well as the fund performance for beneficiaries, retirement corporations and regulatory authorities. The analyses of these data are an important clue for the potential number of beneficiaries and the effectiveness of pension mutual fund investments.[162] Especially performance evaluation is very important for mutual funds and pension mutual funds which are institutional investors, a lot of numerical indices are widely used in the literature (such as Sharpe, Treynor, Jensen and recently Morningstar-star rating). (See Table 1) In this study we use Morningstar-star rating system to conclude performance and rating results of 60 pension mutual funds in Turkey. So we calculate Morniningstar risk adjusted performance and rating results as follows;

Table 1: Study Periods and Other Details

Age of Fund	Morningstar Risk-Adjusted Performance and Star Rating Period Based On	Number of Funds Analysed
1) At least 3 years, but less than 5	100% 3-year raw return.	60
2) At least 5 years, but less than 10	40% 3-year raw return, 60% 5-year raw return.	60
3) At least 10 years	20% 3-year raw return, 30% 5-year raw return, 50% 10-year raw return.	*Non available data and funds

*Turkish pension mutual fund industry commenced on **October 27, 2003**. So there isn't enough data for 10 year.

4.1 Pension Mutual Funds Weighted Performance and Rating Results of Three Year (Weighted 100% Three-Year Raw Return)

We present performance and rating results of Turkish pension mutual funds. So the funds grouped into five categories and ratings weighted 100% three-year raw return.

 (See Table 2) The pension mutual funds which are grouped into Flexible-Balanced Funds, the best performing five star fund is Anadolu Hayat Emeklilik A.Ş. Flexible Income PMF whereas the worst performing one star fund is Koç Allianz Hayat ve Emeklilik A.Ş. Flexible Growth PMF.

Table 2: Flexible-Balanced Funds

Rank	Name of Fund	3 Year Raw Return × 100%	Result	Percent Rank %	Number of Stars

CONCLUSION

A pension mutual fund is a pool of assets forming an independent legal entity that are bought with the contributions to a pension plan for the exclusive purpose of financing future pension plan benefits. The objective for any pension scheme must be to fund the continuation of living standards available in retirement at an acceptable cost. Therefore performance evaluation and rating of pension mutual funds is a necessary and beneficial process which provides performance feedback and signals to pension members about their pension fund investments and retirement benefits.

In developed countries such as US and UK its very important and ethical to evaluate performance of retirement funds (such as 401 (k), IRA or other individual/private retirement accounts) using with different performance techniques. And this technique partly implemented in some developed countries.

In this study we use Morningstar-star rating system in Turkish pension mutual fund industry to show weighted performance and rating results during 3 and 3-5 year periods. Especially Morningstar-star rating system is widely used in the mutual fund industry. But we implemented this technique into Turkish pension mutual fund industry which pension mutual fund industry commenced on 2003.

The pension mutual funds 3 and 3-5 year weighted performance results are summarized as follows;

▪ All pension mutual funds have a negative Morningstar overall performance. This shows that pension mutual funds mostly have lower performance than the 91 day Turkish T-bill rate and also their Morningstar risk is higher than the Morningstar return.

▪ The Capital Asset Pricing Model (CAPM) is consistent with investors (should) require a **higher return** for holding a more risky assets. But in pension mutual funds which are having long-term investment maturities, higher **risk** taking doesn't make any difference **for longer period**. However the stock fund category is showing the best performance in 3 year, liquid and stock funds weighted 3-5 year overall performances are equal.

▪ The best performing pension mutual fund category does not show performance persistancy. For example compared with the other funds average, Stock Funds is the best performing fund category in 3 year, but in weighted 3-5 year the best performing fund category is Gov't Bonds and Bills Funds. Howewer there is a performance persistancy among

the worst categories. Compared with the weighted average of the 3 and 3-5 year, the worst performing fund category is International-Currency Indexed Funds.

▪ The vast majority of the best and worst pension mutual funds show performance persistancy in its category. For example the best 5-star funds in 3 year such as Anadolu Hayat Emeklilik A.Ş. Flexible Income PMF, Koç Allianz Hayat Emeklilik A.Ş. Gov't Eurobond Income PMF and Avivasa Emeklilik ve Hayat A.Ş. Gov't Bonds and Bills Liquid PMF* are still the best performing funds in 3-5 year. Besides the worst performing 1-star funds such as Koç Allianz Hayat Emeklilik A.Ş. ISE 30 Index Specialized PMF, Fortis Emeklilik ve Hayat A.Ş. Gov't Bonds and Bills Income PMF, Avivasa Emeklilik ve Hayat A.Ş. International Composite Income PMF, Fortis Emeklilik ve Hayat A.Ş. Composite Gov't Bonds and Bills Liquid PMF (Temp Acc.) are still the worst performing funds in 3-5 year.

But pension mutual funds performance data quoted represents past performance and this performance results does not guarantee future results. So the **current performance of the fund may be lower or higher than the performance quoted.**

3.5 Corporate Governance

REMUNERATION COMMITTEE, OWNERSHIP STRUCTURE AND PAY-FOR-PERFORMANCE: EVIDENCE FROM MALAYSIA

Wan Nordin Wan Hussin
Basariah Salim

Abstract:

We examine the association between remuneration committee and ownership structures on pay-for-performance. We find that appropriately structured remuneration committee and institutional shareholders enhance the pay-for-performance elasticity. We also find that pay-for-performance relationship is weaker at high level of managerial ownership, consistent with the managerial power model. We show that remuneration committee and institutional investors play important monitoring role in ensuring the interests of executive and shareholder are aligned. The evidence shows that both the principal-agent and managerial power views have relevancy in Malaysia. One of the implications from this study is that investors should be wary of companies that have severe agency problems. These are companies that do not make it transparent that they practice performance-related pay scheme and have very high managerial ownership (agency problem is between controlling shareholders and minority shareholders due to management entrenchment). In such companies there is a possibility that the managers are able to extract rent in the form of excessive pay.

INTRODUCTION

Executive remuneration has become one of the prominent topics in contemporary

corporate governance. The mainstream view, derived from the principal-agent

framework, is that a well designed compensation contract helps to incentivize

executives to enhance shareholder value (e.g., Jensen and Murphy, 1990; Murphy,

1999). Strong pay-for-performance sensitivity is seen as the key metric in aligning the

divergent incentives of executives and shareholders. However, a more skeptical view

sees compensation contract as a perverse instrument of greed rather than a

shareholder-friendly incentive mechanism (Bebchuk and Fried, 2006). One form of

managerial opportunism, or private benefits of control, is when CEOs and top

management awarded themselves stupendous pay-without-performance to the

detriment of shareholders. In other words, the board of directors sets compensation

that deviates from arm's length contracting. Negative coverage on grossly overpaid

top management is regularly featured in the international financial press (Core, Guay,

& Larcker, 2008). Malaysia is not spared. In 2007, angry shareholders of Transmile

Group voted against the payment of directors' fees for the financial year ended 2006

after financial irregularities were made public.[163]

The ample empirical evidence suggests that executive compensation is

largely insensitive to firm performance (e.g., Jensen and Murphy, 1990; Garen, 1994;

Barkema and Gomez-Mejia, 1998; Zhou, 2000; Firth, Fung, & Riu, 2007; Merhebi,

Pattenden, Swan, & Zhou, 2006; Duffhues and Kabir, 2007). This low pay-for-

---

[163] Transmile Group, the air cargo carrier, attracted attention in the early part of 2007 when its external auditor Deloitte & Touche blew the whistle after discovering irregularities in prior years' audited financial statements, involving unsubstantiated sales of more than RM600 million from 2004 to 2006. Subsequently, Transmile Group restated its financial statements from a profit of RM158 million to a loss of RM126 million for the year ended December 2006. In July and November 2007, its former CEO, CFO and two non-executive directors were charged in court with abetting the company in providing misleading financial statements. At the AGM held in September 2007, more than two third of the shareholders voted against the payment of director fees for 2006 totalling RM145,000. The non-executive Chairman of Transmile Group, who is an ex-Transport Minister, resigned shortly before the said AGM. He joined the board of Transmile Group in 2004 when the Kuok Group emerged as a new controlling shareholder.

performance sensitivity raises concern that executives pay arrangements do not provide sufficient incentives to deliver performance or they create agency costs in the form of excess pay (Bebchuk and Fried, 2003).

Given the observed decoupling of pay and performance, a number of studies have attempted to unravel how the pay-for-performance link can be strengthened in order to fulfill the promise of executive compensation as a mechanism to align the interests of executives and shareholders by investigating the role of remuneration committee and ownership structure. Conyon (1997) examines the influence of remuneration committee adoption in UK companies, and finds that, in some circumstances, the adoption lower the growth rates in top director compensation. Conyon and Peck (1998) investigate the affect of outside directors in remuneration committee decisions, and report that they enhance the pay-for-performance sensitivity. However, studies in the US by Anderson and Bizjak (2003) and Vafeas (2003) report insignificant results on the influence of remuneration committee independence towards level of CEO pay. A more recent study by Sun and Cahan (2009) attempts to provide explanation for the mixed findings. Using a broader and richer measure of remuneration committee quality instead of just focusing on independence, they show that the sensitivity of CEO compensation to accounting performance is related to the governance quality of the remuneration committee, for US companies with fully independent remuneration committees.

With respect to ownership structure, Gomez-Mejia, Tosi and Hinken (1987) and Tosi and Gomez-Mejia (1989) document that the responsiveness of CEO pay to performance is greater in owner-controlled firm than management-controlled firm in the US manufacturing sector.[164] A meta analysis of CEO pay studies by Tosi, Werner,

---

[164] Firm is referred as owner-controlled when there is single equity holder who controls as little as 5 percent of the voting stock. Meanwhile, firm is referred as management-controlled when there is no equity holder with at least 5 percent of the stock (Tosi and Gomez-Mejia, 1989).

Katz and Gomez-Mejia (2000) concludes that firm size rather than performance is the strongest predictor of CEO pay in management-controlled firms, while performance-related pay is more prevalent in for owner-controlled firms. Further evidence on the importance of ownership structure in the pay-for-performance linkage for countries in Asia is provided by Firth et al. (2007) and Kato and Long (2005). Their studies show that in China, the pay-for-performance link is weaker or insignificant in listed firms owned by the state bureaucracy. Meanwhile, Kato, Kim and Lee (2007) document that pay-for-performance link is significant for Korean non-Chaebol firms but negligible for Chaebol firms.

Denis and McConnell (2003) suggest that the interrelationship between executive compensation and corporate governance mechanisms remains a fruitful area for research worldwide. Bruce, Buck and Main (2005) suggest that country-level institution should be factored into in analyzing executive pay. Furthermore, Kabir (2008) observes that not much is known about how firms across the world reward their executives outside the US, primarily due to the lack of publicly available information on executive pay and very intensive data collection requirements. We continue this line of research and investigate whether internal governance mechanisms, particularly the remuneration committee structure and ownership structure, influence the pay-for-performance link using a unique data set on remuneration practices and directors' remuneration in Malaysia.

In addition, this study is also motivated by Conyon (2006) who challenged researchers to distinguish between the two competing theories of executive compensation namely the principal-agent and managerial power. Thus, our study also attempts to disentangle the managerial power and principal-agent views of executive pay. As mentioned earlier, the principal-agent (or optimal contracting) view of executive compensation holds that a well designed incentive contract whereby

managers are suitably rewarded for generating shareholder value helps to closely align the interests of managers and shareholders (e.g., Jensen and Murphy, 1990; Core, Holthausen and Larcker (1999). However, Bebchuk and Fried (2003) argue that the promise that managerial incentive contract is a partial solution to the agency problem remains largely unfulfilled. Bebchuk and Fried (2003) are of the view that executive compensation exacerbates the agency problem by promoting rent-extracting on the part of the executives. In their alternative managerial power story on executive compensation, powerful CEOs have great sway over their own pay by capturing the board, resulting in rent extraction in the form of greater CEO pay, or pay-without-performance, to the detriment of shareholders.

Malaysia provides a unique setting to examine the applicability of managerial power and principal-agent views in the determination of executive pay. Following the introduction of the voluntary Malaysian Code on Corporate Governance (MCCG) in 2000, companies listed on Bursa Malaysia are required to make public the Statement of Corporate Governance incorporating disclosure on directors' remuneration. The MCCG emphasizes the following principles on directors' remuneration. Firstly, in the case of executive directors, remuneration should be structured so as to link rewards to corporate and individual performance. Secondly, companies should establish a formal and transparent procedure for developing policy on executive remuneration and for fixing the remuneration packages of individual directors. And thirdly, company's annual report should contain details of the remuneration of each director. Under best practices in corporate governance, the MCCG recommends companies to establish a remuneration committee consisting of wholly or mainly non-executive directors. The committee is allowed to get an advice from consultant relating to executive directors' remuneration and recommend to the board an appropriate remuneration for the executive directors.

By exploiting the enhanced disclosures on the activities of remuneration committees and directors' pay, and whether the companies observe the corporate governance principle by linking executive pay to performance, we expect that companies are subject to the dark side of managerial power when they do not subscribe to performance-related pay scheme and at high level of managerial ownership, level of pay is an increasing function of managerial ownership. Specifically, the objectives of this study are (1) to examine whether companies that publicly disclosed that they subscribe to the MCCG's principles in structuring the executive remuneration so as to link rewards to corporate and individual performance actually practice what they preach, (2) to examine whether strong remuneration committee structure enhances the pay-for-performance link, (3) to examine whether ownership structures influence the pay-for-performance link.

Using data from 2003-2005, our results show that companies that claim that their reward system is related to performance, generally 'do what they say', and companies with strong remuneration committees appear to design their executive pay packages so as to reward their executives for creating shareholder value. It appears that institutional investors are associated with higher pay-for-performance relationship. The pay-for-performance relationship seems to weaken when managerial ownership exceeds 35 percent, possibly due to the dark side of managerial power.

Our study contributes to executive pay-for-performance literature in a few ways. Firstly, we extend the measurement of the governance quality of remuneration committee by including the activities of the remuneration committees. And secondly, we show that in situation where managerial power is at its most destructive, when companies have very high managerial ownership and at the same time they do not

1021

subscribe to performance-related pay scheme, rent extraction by executives in the form of excessive pay is likely.

The paper is organized as follows. The next section summarizes the prior literature on pay-for-performance link and develops the hypotheses to achieve our research objectives. This is followed by a description of the pay-for-performance model. Next, we explain the sample selection and data sources. The penultimate section presents the results and the final section concludes the paper and discusses the implications of our study for the governance of publicly traded companies.

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

Pay-for-Performance Link

There is a copious literature on executive remuneration studies using the principal-agent framework. In this framework, shareholder (principal) expects the executive (agent) to put their greatest effort to maximize firm value, which in turn increases the shareholder's wealth. In ensuring that the alignment exists, the theory maintains that firms seek to design the most efficient compensation packages possible in order to attract, retain and motivate executives (Conyon, 2006).

The empirical study by Jensen and Murphy (1990), considered as one of the most comprehensive, has produced dismal results on the pay-for-performance alignment, which justifies shareholders' disquiet on the issue of pay and performance. They conclude that there is little support for agency theory notions that optimal contracting aligns executive and shareholder interests. Other studies have also failed to provide strong confirming evidence on the association of pay and

performance such as Tosi and Gomez-Mejia (1994), Barkema and Gomez-Mejia (1998) and Jensen and Murphy (2004).

Recently, discussion on executive remuneration issues has shifted from the dominance of optimal contract (principal-agent theory) to managerial power theory (Barkema and Penning, 1998; Bebchuk, Fried, & Walker, 2002; Bebchuk and Fried, 2003; 2004). Bebchuk and Fried (2003; 2004) and Bebchuk et al. (2002) claim that CEOs have too much power over their boards. Compensation contracts are not negotiated at arm's length as they would be if shareholders were at the bargaining table, because board members care more about their standing with the CEO than with the shareholders. The lack of arm's length bargaining has resulted in excessive pay levels, weak pay-for-performance relationships, and inefficient forms of pay.

In Malaysia, realizing the importance of executive remuneration as a mechanism in aligning the interest of shareholder and executive, the MCCG strongly advocates the alignment between executive pay and performance. Some companies do in fact make a clear positive statement that they practice performance-based pay in the annual reports, while others are silent about it. Appendix 1 provides two examples of the performance-based pay disclosures, or lack of it, extracted from the Statements of Corporate Governance of the two companies. Our first research question, which is to ascertain whether companies that claim they follow performance-based pay actually practice it, leads to the following hypotheses:

Hypothesis (H_1): Companies that disclose that they reward executive directors based on firm or individual performance have stronger pay-for-performance relationship.

Remuneration Committee Structure and Performance-Related Pay

Many prominent scholars in agency theory and remuneration studies like Jensen and Meckling (1976), Fama (1980), Fama and Jensen (1983), Jensen and Murphy (1990; 2004) argue that corporate governance mechanisms in the form of incentive (i.e. remuneration) or monitoring (i.e. ownership structures and board characteristics) are important in aligning the interest of shareholders and executives. The theory presumed that effective boards of directors have effect on executive remuneration given that they have the authority mandated by the shareholders to look into the matter of executive remuneration. The board of directors, particularly through its remuneration committee, is involved in designing a desirable remuneration package for executives in line with governing objective, and the corporate vision and strategy of company (Jensen and Murphy, 2004). Jensen and Murphy (2004) argue that corporate governance and remuneration policies are highly inter-related where bad governance can easily lead to value-destroying pay practices. They propose a number of recommendations particularly on the roles and functions of remuneration committee in pay-setting process. These include remuneration committees must take full control of the remuneration process, policies and practices, remuneration committees should employ their own professional contracting agents when hiring new top-level managers, remuneration committees should give careful consideration to issuing executive stock options with exercise prices that increase with the company's cost of capital, etc.

In ensuring its effectiveness, the remuneration committee should be independent from executives' influence and its members should be exclusively non-executive directors. Murphy (1999) observes that most large US corporations have a compensation committee consisting of two or more independent directors. However, Bebchuk and Fried (2003) cautions that normally independent directors are proposed

and nominated as board members by the influence of executive directors. Thus, to what extent the non executive directors can be truly independent is an open question. The obstacles to achieving a truly independent remuneration committee include the following: (1) CEO often nominates non-executive directors, (2) non-executive directors must rely on the executives for most of the information they receive, (3) non-executive directors need good relationships with the executives if they are to function well in guiding corporate policy, (4) non executive directors often share a similar backgrounds and interest with executive directors, and frequently, they themselves are senior executives in other companies.

Vafeas (2003) examines the relation between insider membership in remuneration committees and CEO remuneration, and finds a steady decline in the number of committees with insider participation, and opportunistic behavior by insiders in setting pay. However, Anderson and Bizjak (2003) find little evidence that greater remuneration committee independence affects executive remuneration. Moreover, their findings show that committee consisting of insiders or the CEO does not award excessive remuneration or lower overall incentives. They also find no evidence that pay decreases or total incentives increase when CEOs come off the remuneration committee.

UK studies by Conyon (1997), Conyon and Peck (1998), Laing and Wier (1999), and Ezzamel and Watson (2002) document the invaluable role of the remuneration committee. Conyon (1997) and Laing and Wier (1999) show that the existence of remuneration committee influences the pay level of top directors. Conyon and Peck (1998) suggest that remuneration committee independence influences pay-for-performance sensitivity. Ezzamel and Watson (2002) show that remuneration committee plays important roles in executive pay-setting process. Their results suggest that members of remuneration committees in the UK tend to

determine CEO pay awards on the basis of: (1) their own pay levels, (2) the percentage change (typically increase) in their own pay awards, and (3) an element which attempts to maintain parity with comparable CEOs in other firms. On the other hand, Conyon and He (2004) find that the presence of significant shareholders on the remuneration committee is associated with lower CEO pay and higher CEO equity incentives. Firms with higher paid remuneration committee members are associated with greater CEO compensation and lower equity incentives. Nevertheless, they find no evidence that insiders or CEOs of other firms serving on the remuneration committee raise the level of CEO pay or lower CEO equity incentives.

The latest study by Sun and Cahan (2009) provides an important insight that CEO compensation is more positively associated with accounting earnings when companies have high remuneration committee quality. Based on the above empirical results and discussions, we hypothesized the following:

Hypothesis (H2): Companies with good remuneration committee structures have stronger pay-for-performance relationship than their counterparts with poorly structured remuneration committee.

Ownership Structure and Performance-Related Pay

Ownership structure is another important corporate governance mechanism in aligning the interest of shareholders and executives from an agency theory perspective (Jensen and Meckling, 1976; Fama and Jensen, 1983; and Hart, 1995). Jensen and Meckling (1976) theorize that stock ownership by management could reduce agency problems. As their stakes rise, managers pay a larger share of

agency costs and, therefore, are less likely to expropriate wealth from other stockholders.

A number of studies show that managerial ownership significantly influences the level of executive pay and pay-for-performance relationship although the results are mixed. Core et al. (1999) find that CEO remuneration is a decreasing function of the CEO's ownership stake and the existence of an external blockholder who owns at least 5 percent of the equity. Brick, Palmon, and Wald (2006) find that the higher the percentage owned by the CEO, the lower the levels of CEO remuneration and the lower the fraction of non-cash compensation received.

On the other hand, Holderness and Sheehan (1988) provide evidence that executives who are majority shareholders (defined as individuals owning at least half but not all of the common stock) in publicly held corporations receive marginally higher salaries than other officers. Zingales (1995) shows stronger evidence of executives using their controlling position in their firms to pay themselves more. He examines the remuneration as a proxy for private benefit of the largest shareholder in companies with differential voting rights. He finds that such shareholders, who are typically the CEO, are paid significantly more and that the amount is correlated with their voting power. The evidence supports the "skimming" view of managerial remuneration as it suggests that such executives are paying themselves more.

Similar to Holderness and Sheehan (1988) and Zingales (1995) evidence in the US, Mitsudome (2000) finds that the level of compensation increases as the level of managerial ownership increases among Japanese firms, suggesting that firms with a higher level of managerial ownership experience greater agency problems. Mitsudome (2000) finding is supported by another research using Japanese data by

1027

Basu, Hwang, Mitsudome and Weintrop (2007). Basu et al. (2007) find that top executive pay is higher in firms with weaker corporate governance mechanisms. They use management ownership and family control, keiretsu affiliation, the presence of outside directors and board size to measure corporate governance.

A study by Cheung, Stouraitis, and Wong (2005) in Hong Kong finds a positive relationship between managerial ownership and CEO cash emoluments for levels of managerial ownership of up to 35 percent in small market cap firms and in family controlled firms, and up to 10 percent in large firms. They further suggest that in the presence of information asymmetry between owners-managers and outside investors (which are likely in small firms), the former may use their ownership rights to extract higher salaries for themselves.

The mixed evidence on the association between ownership structure and pay-for-performance relationship points to the relevance of both the managerial power and principal agent views of CEO compensation. The challenge is to disentangle the two. Thus, we formulate the following hypotheses in resolving this issue.

If principal agent view is more dominant, then we expect that the pay-for-performance relationship is increasing with higher level of managerial ownership, as hypothesized in H3a.

Hypothesis (H3a): The pay-for-performance relationship is stronger as managerial ownership increases.

However, this relationship may disappear at high level of managerial ownership due to the dark side of managerial power, as hypothesized in H3b.

Hypothesis (H3b): The pay-for-performance relationship is weakening at extremely high level of managerial ownership.

Apart from managerial ownership, another important dimension of corporate ownership is the substantial shareholdings by non-management blokcholders, typically institutional shareholders. The literature predicts that blockholders will be more active monitors of management than atomistic shareholders because they have more to gain from improved firm performance. The benefits the large blockholders derive from the monitoring activities are more likely to exceed the costs that they incur (Shleiffer and Vishny, 1986).

In the US, Cordeiro and Veliyath (2003) show that the number of blockholders holding more than 5 percent of the outstanding shares is negatively related with CEO cash remuneration but not total pay. Khan, Dharwadkar, and Brandes (2005) investigate how institutional ownership concentration and dispersion affect levels of CEO remuneration, pay mix and stock option pay sensitivity. They find that the percentage of shareholding by the largest institutional investor is associated with lower level of CEO remuneration, but that the number of blockholders holding more than 5 percent of the outstanding shares does not predict any aspects of CEO remuneration. In addition, institutional ownership dispersion is associated with increased level of remuneration. These results suggest that increases in institutional ownership concentration promote monitoring due to the needs and abilities of large institutional owners. However institutional ownership dispersion negates the beneficial effects of institutional ownership. Additionally, Hartzell and Starks (2003) find that institutional ownership concentration is positively related to the pay for performance sensitivity of executive remuneration and negatively related to the level of remuneration, even after controlling for firm size, industry, investment opportunities

and performance. They show that, for an average executive, an increase in one standard deviation in the percentage of shareholdings by the top five institutional investors is associated with (i) a greater than 20 percent increase in the sensitivity of changes in total compensation to changes in shareholder wealth, and (ii) a drop in total compensation equal to 19 percent of the sample mean.

Ozkan (2006) is one of the earliest studies that examine large non-management ownership and CEO pays the UK. He observes that institutional ownership and non- managerial and non-board-member blockholder ownership have negative impact on CEO compensation, which points to their active monitoring role. There are other studies that look at the association between ownership structures and executive remuneration in countries with high family ownership such as Hong Kong and Malaysia. Firth, Tam, and Tang (1999), using Hong Kong data, report that high institutional shareholdings are associated with lower remuneration levels. They argue that top management probably feels more constrained in engaging in self-serving behavior because of the monitoring role of institutional shareholders. A subsequent study by Cheng and Firth (2005), also using Hong Kong data, shows that institutional ownership moderate remuneration of top management. Using Malaysian data, Dogan and Smyth (2002) show a weak negative relationship between board remuneration (salaries and fees paid to all directors) and ownership concentration (a dummy variable equals 1 if the percentage of shares owned by the largest shareholder is above the median).

Kato and Long (2005), Kato et al. (2007) and Firth et al. (2007) provide further evidence on how ownership structures can strengthen or weaken the pay-for-performance link in countries with unique government ownership like China and South Korea. Kato and Long (2005) show that state ownership of China listed firms is weakening the pay-for-performance link for top managers. Firth et al. (2007) find

statistically significant pay-for-performance coefficients when the controlling shareholder is a Chinese State-Ownership-Enterprise (SOE) or private blockholder. In addition, firms with foreign investors have significant pay-for-performance sensitivities. In contrast, performance is not statistically related to change in CEO compensation for firms whose controlling shareholder is a Chinese state bureaucracy. Kato et al. (2007) estimate the pay-for-performance relations for executives of Korean firms with and without Chaebol affiliation.[165] Their result reveals non-Chaebol firms drive the significant executive pay-for-performance link. No such link is found to exist for Chaebol firms. Based on the above, we posit the following:

Hypothesis (H3c): The pay-for-performance relationship is stronger in companies with higher non-management blockholder ownership.

MODELING PAY-FOR-PERFORMANCE

Following Murphy (1999), Zhou (2000) and Merhebi et al. (2006), the pay-for-performance elasticity is measured by regressing the dependent variable (change in log of executive remuneration) on the independent variables, log of (1 + contemporaneous return) and log (1 + lagged return). The model is:

$$\Delta \ln PAY_{it} = \alpha + \beta_1 \ln(1+RET_{it}) + \beta_2 \ln(1+RET_{it-1}) + u_{it}$$

where PAY = total executives pay, and

RET= <u>stock price at period t - stock price at period t-$_1$ + dividends at period t</u>

stock price at period t$_{-1}$

---

[165] Chaebol refers to several dozen large, family-controlled Korean corporate groups, assisted by government financing, which have played a major role in the South Korean economy since the 1960s. Some have become well-known international brand names, such as Samsung, Hyundai and LG (Life's Good)

The formula is similar to the one used by Zhou (2000). Stock price and dividend data are taken from Datastream. The self-computed annual rate of return (RET) in this study is similar to Return Index (RI) data from Datastream.

In testing hypothesis H1 the sample is partitioned into two subgroups according to whether the corporate governance statement disclosed that the pay is linked to performance or otherwise (performance based versus non-performance based subgroups). For hypothesis H2, the sample is divided into two subgroups, those with good or poor remuneration committee structures using the median score for remuneration committee structure as cutoff point. Meanwhile, for hypotheses H3a, H3b and H3c, the sample is divided into various subgroups according to levels of managerial ownership, local institutional ownership and foreign ownership. Kato et al. (2007) and Firth et al. (2007) use similar methods when assessing the pay-for-performance sensitivity between chaebols and non-chaebols in South Korea and various types of ownership in China.

SAMPLE AND DATA

This study uses pooled cross-sectional and time series data. The executive remuneration and corporate governance data are taken from the annual reports of the selected Bursa Malaysia listed companies for years 2003 to 2005. The 2003-2005 periods is chosen because the disclosures as required under the MCCG are effective for annual reports after June 2001. As at January 2006, slightly over 1,000 companies were listed on Bursa Malaysia comprising 646 on Main Board, 269 on Second Board and 110 on MESDAQ[166]. This study excludes MESDAQ, PN4[167] and

---

[166] The MESDAQ market was created in March, 2002 as a unique market with a separate identity from the Bursa Malaysia Main and Second Boards, specifically for the capital-raising needs of technology and high-growth potential companies. The minimum paid up capital is RM2 million for technology and non-technology companies, and a minimum of RM20 million for technology incubator companies.

PN17[168] companies. MESDAQ companies are excluded since their issued and paid-up capital is considered small compared to companies on Main and Second Boards[169]. In addition, PN4 and PN17 companies are excluded due to their adverse financial conditions.

Out of the 876 remaining companies, a further 409 companies are eliminated due to changes of financial year end, de-listing, incomplete annual reports for the three consecutive years 2003 to 2005, difficulties in assessing the annual reports online, and anomalous data. The sample of 476 remaining companies is further reduced if there is unclear or no separation between executive and non-executive remuneration in the annual report. This segregation is important since this study focuses on the executive remuneration where the bulk of total directors pay goes to the executive directors[170]. Taking this into consideration, 372 companies are used as a sampling frame for this study. Due to the intensive and time consuming nature of hand collecting the executive remuneration and corporate governance data, 200 companies are chosen out of the 372 companies. Due to unavailability of data from Datastream or conflicting data between Datastream and annual reports, the final sample is reduced to 158 companies.

---

[167] PN4 companies are companies which failed to meet the criteria set out under the Bursa Malaysia's "Practice Note No. 04/2001" as follows:

  i.   The company failed to report the deficit in its combined shareholders funds;
  ii.   Receivers or Managers have been appointed to manage the asset of the relevant company / its subsidiaries properties / associate companies;
  iii. Auditors have given a "disclaimer opinion" regarding the companies outlook in the company's latest accounts;
  iv.   A special manager has been appointed as provided for under the Danaharta Nasional Berhad Management Act 1998.

[168] PN17 companies are PN4 companies which are being restructured and get into trouble again and the situation is not rectified.

[169] Issued and paid-up capital for Main Board and Second Board must have a minimum of RM60 million and RM40 million respectively.

[170] Non-executive director remuneration which basically comes from fee is also taken during data collection process. Our data show that on average, 90% of director remuneration is from executive directors and about 10% from non-executive directors.

The items extracted from the annual reports on remuneration committee characteristics are based on the Standard and Poor's Governance Disclosure Scorecard 2004 (SPGDS) which reflects the global best practices of corporate governance. In the SPGDS there are 34 items under remuneration matters. However, for this study, in measuring the strength of the remuneration committee structure, only 15 items are selected as the others are not available from the Statement of Corporate Governance disclosed in the annual reports of Malaysian companies. The items included and excluded to indicate the strength of the remuneration committee structure are shown in Appendix 2.

FINDINGS

Descriptive Statistics

Table 1 describes executive pay and return on stock for the sample companies for 2003 to 2005, partitioned by performance-based companies and non-performance-based companies. For our sample, the ratio between these two groups is approximately 63 percent to 37 percent for each of the years. Comparing between performance-based companies and non-performance-based companies, the table shows that the former group has lower average executive pay, although it generates better market performance. Average executive pay has increased steadily in each year for both groups, from RM2 million in 2003 to RM2.4 million in 2003 for the performance-based companies, and from RM3.1 million in 2003 to RM3.7 million in 2005 for the non-performance-based companies. On the other hand, return on stock has steadily declined for both groups over the period 2003-2005. In the performance-based companies, it declined from 26 percent in 2003, to 16 percent in 2004 to -10 percent in 2005. The corresponding figures for the non-performance-based companies were 18 percent, 10 percent and -17 percent. The maximum total pay for the non-performance-based group

(RM79 million) is considerably higher than the performance-based group (RM19 million).

Table 1: Descriptive Statistics of Executive Remuneration and Return on Stock for 2003 to 2005 Partitioned by Performance-Based Companies and Non-Performance-Based Companies

Table 2 describes the remuneration committee (panel A) and share ownership (panel B) of the sample companies. Nearly 90 percent of the sample companies have established remuneration committees. Slightly more than two-third of remuneration committee members are independent directors. The percentage of companies with all independent directors on the remuneration committee has

increased slightly from 12 percent in 2004 to 15 percent in 2005. About 40 percent of sample companies disclose the frequency of remuneration committee meeting. However, less than half of these companies disclose in details the attendance by each of the members. Nearly one-third of sample companies hire external compensation specialists to ascertain industry pay practices. As mentioned earlier, 63 percent of sample companies state categorically that they practice performance-related pay scheme. Less than 50 percent of sample companies use long term performance incentive. Nearly 20 percent of sample companies do not disclose executive pay in the band of RM50,000 as stipulated by the Listing Requirements of Bursa Malaysia[171]. And less than 15 percent of sample companies disclose the pay for individual executive director. For the sample companies, the scores for remuneration committee structure range from 1 to 15 with a mean and median of 7.19 and 7.25 (not tabulated) respectively.

---

[171] **In relation to director's remuneration, the Code highlighted the issue under its principles and best practices parts. The principles part addresses three items, which are level and make-up of remuneration, procedure, and disclosure in annual report. With respect to executive remuneration, the principle of the Code required the following: -**

1. The level and make-up of remuneration (in the case of executive directors, the component parts of remuneration should be structured so as to link rewards to corporate and individual performance);
2. Procedure (companies should establish a formal and transparent procedure for developing policy on executive remuneration and for fixing the remuneration packages of individual directors);
3. Disclosure (company's annual report should contain details of the remuneration of each director).

Moreover, although the Code is a voluntary requirement, Chapter 15, para 15.26 of the Listing Requirement makes it compulsory for companies to disclose on the extent of compliance with the best practice set out in the Code, while allowing for some flexibility in its implementation. With respect of remuneration, first, companies are required to disclose the aggregate remuneration of directors with categorization into appropriate components (e.g. directors' fees, salaries, percentages, bonuses, commission, compensation for loss of office, benefits in kind based on estimated money value) distinguishing between executive and non-executive directors in their annual report. Second, companies are also required to disclose the number of directors whose remuneration falls in each successive band of RM50,000 distinguishing between executive and non-executive directors as well.

Findings on Pay-for-Performance Elasticity

Table 3 summarizes the pay-for- performance relationship for the performance-based pay subgroup (column 2), non-performance-based pay subgroup (column 3) and for the full sample (column 4). Both columns 2 and 3 provide evidence in support of H1, whereby the sum of the coefficients of B_1 (change in shareholder wealth in period t) and B_2 (change in shareholder wealth in lagged period t – 1) is higher for the performance-based pay subgroup than the non-performance-based pay subgroup. Column 2 shows moderately significant and positive coefficients for both changes in current year's and previous year's shareholder wealth. Summing both coefficients, this study finds a pay-performance elasticity of 16.4 percent for the performance-related pay companies.   This study interprets the result as follow: executives in companies that have pay-performance scheme receive a 1.64 percent increase in remuneration for a 10 percent increase in shareholder wealth. The result shown in column 3 indicates that there is no significant relationship between changes in executive pay and changes in current and previous year market-based performances.

This result again supports H1, that non-performance based companies do not link their executive pay to firm performance. In sum, Malaysian companies generally 'do what they say'. When companies make a positive declaration in the annual reports that they adopt performance-related pay scheme, these disclosures are generally reliable.

Table 3 : Pay-Performance Elasticity Partitioned by Performance-Based Pay and Non-Performance-Based Pay Companies and Full Sample

Variables (1)	Performance Based (2)	Non-Performance Based (3)	Full Sample (4)
Constant	0.063***	0.036	0.055***

N	198	118	316

t-statistics are in parentheses. ***, ** and * denote significance at the 0.01, 0.05 and 0.1 level

Column 4 shows the result of pay-for-performance elasticity for the full sample. The result shows that the coefficient on the previous year's change in shareholder wealth is positive and statistically significant at the 5 percent level. However the coefficient for current year's change in shareholder wealth is insignificant. The combined coefficients imply that the executives receive a 1.34 percent increase in remuneration for a 10 percent increase in shareholder wealth. The 13.4 percent pay-for-performance elasticity in Malaysia is comparable to the evidence in Canada (16 percent) and Australia (11.6 percent) as provided by Zhou (2000) and Merhebi et al. (2006), respectively. Further, Rosen (1992) estimates that the elasticities of top executive pay with respect stock market returns are between 10 to 15 percent. On the other hand, based on S&P 500 Industrials companies, Murphy (1999) demonstrates that pay-for-performance elasticities in the US have nearly

tripled from 9 percent in the 1970s to 26 percent during the first seven years of the 1990s.

Table 4 provides evidence in support of H2 whereby companies with good remuneration committee structures have stronger pay-for-performance relationship. The result in column 2 which represents companies with good remuneration committee structures reports a positive and statistically significant coefficient for previous year's change in shareholder wealth. The combined coefficients for changes in current and previous year shareholder wealth is 0.2. This result can be interpreted as executives in companies with good remuneration structure receive a 2.0 percent increase in remuneration for a 10 percent increase in shareholder wealth. As expected, column 3 which represents companies with poor remuneration committee structures show insignificant coefficients for both changes in shareholder wealth. In sum, the results in columns 2 and 3 of Table 4 support H2, whereby the pay-for-performance elasticity for companies having good remuneration committee structure is higher than their counterparts with poor remuneration committee structure (20 percent versus 8 percent) . This implies that remuneration committee structure is an important factor in aligning the pay-for-performance relationship as proposed by the agency theorists such as Jensen and Murphy (2004). They argue that remuneration committee plays an important role in dealing with matters specifically related to executive remuneration on behalf of shareholders and executives. In addition, these results reinforce the MCCG's recommendations on the establishment and role of remuneration committee in aligning the interest of shareholders and executives.

The following paragraphs report and discuss results of pay-for-performance elasticities for different ownership structures, to provide answers for H3a, H3b and H3c. Table 5 show the pay-for-performance elasticiticities at various levels of managerial ownership. Following Morck et al. (1988) and Cheung et al. (2005), managerial ownership is partitioned into three subgroups; less than 10 percent, between 10 to 35 percent and above 35 percent. The results of Table 5 reveal that different levels of managerial ownership have different impact on the pay-for-performance elasticity.   Column 2 shows a statistically significant relationship between change in executive remuneration to contemporaneous change in shareholder wealth at 5 percent level for managerial ownership less than 10 percent. Including the coefficient on the previous year performance variable, the total elasticity is 0.156.

In addition, the pay-for-performance relationship is also statistically significant for level of managerial ownership between 10 to 35 percent. For this managerial ownership group, the relationship is significant for the lagged performance variable. Total coefficient for both variables is 0.115. However, column 4 which represents level of managerial ownership above 35 percent does not provide statistically

significant pay-for-performance link. In sum, the results of columns 2, 3 and 4 partly supports H3a. There seems to be a significant pay-for-performance link for managerial ownership up to 35 percent[172]. However, for extremely high managerial ownership, the link of pay-for-performance disappears as shown in column 4. Although not tabulated in table 4, when we run regression on determinants of level of pay by regressing the log of total executive pay on market and accounting performance measures such as return on stock and return on assets, and piecewise managerial ownership variables (less than 10 percent, 10 to 35 percent, and more than 35 percent), we find that for non-performance-based subgroup, level of pay is positively associated with managerial ownership above 35 percent. This evidence, coupled with the result in column 4 implies that when managerial ownership exceeds 35 percent, the executives tend to use their power in extracting more pay without linking the pay to performance as argued by the managerial power approach. To sum up, the results as shown in columns 2, 3 and 4 seem to suggest that different level of managerial ownership has different influence on the pay-for-performance relationship.

Table 5 : Pay-Performance Elasticity Partitioned by Levels of Managerial Ownership

Variables	Managerial Ownership		
	Below 10 percent (2)	10 to 35 percent (3)	Above 35 percent (4)

---

[172] Beside managerial ownership less than 10%, 10% to 35% and above 35%, this study uses a variety of turning points for managerial ownership (less 10%, 10% to 50% and above 50%; less 5%, 5% to 25% and above 25%; and less 5%, 5% to 35% and above 35%). However, the results are qualitatively similar eventhough different turning points have been used.

Table 6 analyses the pay-for-performance link for various non-managerial blockholder ownerships to test H3c. The non-managerial blockholder ownerships are local institutional investors and foreign investors. For each of the non-managerial blockholder ownerships, the cutoff used is 5 percent, following Conyon and He (2004) and Tosi and Gomez-Mejia (1989).

Columns 2 and 3 show that pay-performance relationship is stronger for local institutional ownership above 5 percent than below 5 percent (0.179 versus 0.107). This implies that higher local institutional ownership generates larger pay-for-performance elasticity. Similar result is obtained for foreign ownership. Column 4 reports combined pay-for-performance elasticity of 0.151 for foreign ownership of at least 5 percent, which is higher than the combined pay-for-performance elasticity of 0.122 for foreign ownership less than 5percent.

Table 6 : Pay-Performance Elasticity Partitioned by Levels of Non-Managerial Ownership

Variables	Local Institutional Ownership		Foreign Ownership	
	ABOVE 5 percent	BELOW 5 percent	ABOVE 5 percent	BELOW 5 percent
(1)	(2)	(3)	(4)	(5)

N	161	155	98	218

t-statistics are in parentheses. ***, ** and * denote significance at the 0.01, 0.05 and 0.1 level

In sum, the results in Table 5 support H3c whereby pay-for-performance elasticity is stronger in companies with higher local institutional and foreign ownership. These results are consistent with other studies that show ownership matters in aligning the interests of shareholders and investors through the use of pay-performance incentive. A study by Kato et.al. (2007) reports that non-Chaebol

firms drive the significant link between pay and performance in Korea. Kato and Long (2005) report that state ownership of China listed firms weakens the pay-performance link. Firth et al. (2007) reports that foreign owned firms in China have higher pay-performance sensitivity.

CONCLUSION

The salient findings can be summarized as follows. First, companies that claim that their reward system is related to performance, generally 'do what they say'. Second, companies with appropriately structured remuneration committee do reward their executives for creating shareholder value. Third, companies with managerial ownership below 35 percent appear to use performance-based pay, and the pay-performance incentive is stronger for the below 10 perc ent group than the 10 to 35 percent group. On the other hand, executives in companies with high managerial ownership (above 35 percent), tend to use their power in extracting more pay. It is important to emphasis that in the context of Malaysia the incentive mechanism (i.e. pay-for-performance) and monitoring mechanism, in particular the remuneration committee structure and ownership structure, work hand in hand in aligning the interests of shareholders and executives. Overall, as reflected by the significant coefficient for the entire sample, there is statistical evidence that change in executive pay in Malaysia is associated with performance. This is consistent with the recommendation of the Malaysian Code on Corporate Governance and the in line with international practices.

Due to unavailability of data related to the value of stock options granted to and exercised by executives, this study ignores share-based payment in measuring the executive remuneration. With the adoption of the new accounting standard FRS 2 in 2006, which requires companies to expense stock options, it is instructive to

ascertain whether the above findings are robust to the inclusion of stock options in the total remuneration package.

Appendix 2: Remuneration Committee Attributes and Executive Pay Practices

1*	Does the company have a remuneration committee (RC)?
2	Is the remuneration committee members disclosed?
3*	Is the majority of RC independent?
4*	Are all members of the RC independent?
5*	Is the RC chaired by an independent non-executive director?
6*	Is disclosure made of individual members' attendance at the remuneration committee meetings?
7*	Does the company disclose the frequency of remuneration committee meeting in the annual report?
8	Did the RC meet more than 2 times in the year?
9	Did the RC meet more than 4 times in the year?
10	Was the attendance at the RC meetings more than 60 percent?
11	Was the attendance at the RC meetings more than 80 percent?
12	Was the attendance at the RC meetings 100 percent?
13	Is at least one remuneration committee member knowledgeable about executive compensation?
14*	Does the RC recommend to the board a framework of remuneration for the board and key executives?
15	Does the remuneration committee determine specific remuneration packages for executive directors and the CEO?
16	Are the remuneration committee's recommendations submitted for endorsement by the entire board?
17*	Does the RC's review include all aspects of remuneration (such as salaries, fees, allowances, bonuses and options?
18*	Is disclosure made of the RC's processes (e.g., external compensation specialists hired) to ascertain industry practices and salary levels for pay and employment conditions?
19*	Is executive director compensation linked to industry, company and/or individual performance?
20	Is the percentage of performance-related elements of executive directors' remuneration above 50 percent?
21	Is compensation of non-executive directors linked to their level of contribution and responsibilities, and time spent and effort?
22	Were industry experts consulted on the remuneration of non-executive directors?
23	Has the board recommended all components of non-executive director compensation for approval at the annual general meetings?
24	Do service contracts for directors contain onerous removal clauses?
25	Did the remuneration committee consider the appropriateness of compensation commitments for early termination of directors?
26*	Are directors prevented from deciding on their own remuneration?
27*	Does director remuneration include long-term incentives? (E.g., bonuses payable after 12 months and/or share option with a vesting period > 12 months)
28*	Is disclosure made to shareholders of remuneration of executive directors in bands of RM50,000?
29	Is disclosure made to shareholders of remuneration of non-executive directors?
30	Is disclosure made to shareholders of remuneration of top 5 executives who are not directors?
31*	Is disclosure made of components of remuneration analyzed by salaries, variable bonuses, options and long-term incentives?
32*	Is disclosure made of remuneration of each director by name?
33	Is disclosure made of remuneration to an employee who is an immediate family member of a director or the CEO, and whose own remuneration exceeds $150,000? If there are

	no such an employees is this disclosed?
34	If the company has any shares/options for employees/directors, are the details of these disclosed (shares issued to employees or options granted)? If it does not have such schemes, is this fact disclosed?

Note: For item 28, the quantum RM50,000 is adapted for item 28 to suit the local requirement. Only items marked * are included in this study to compute the remuneration committee structure score.

Appendix 1 : Disclosure and Non-disclosure of Performance-Related Pay in Annual Reports

Company	2005	2004	2003
A Company that makes a positive statement that it uses performance-related pay scheme for executive directors	The framework for the remuneration of the Executive and Non-Executive Directors are reviewed regularly against market practices. As an Executive Director, the Group CEO is paid a salary, allowances, bonuses and other customary benefits as appropriate as a senior management member. Salary reviews take into account market rates and the performance of the individual and the Group.	The Executive Directors' remuneration comprises a salary, allowances, bonuses and other customary benefits as appropriate. Salary reviews take into account market rates and the performance of the individual and the Group.	The Executive Directors' remuneration comprises a salary, allowances, bonuses and other customary benefits as appropriate. Salary reviews take into account market rates and the performance of the individual and the Group.
A Company that does not make a positive statement that it uses performance-related pay scheme for executive directors	The Company has adopted the objectives as recommended by the Malaysian Code on Corporate Governance to determine the remuneration of Directors so as to ensure that the Company attracts and retains the Directors needed to run the Company successfully.	The Company has adopted the objectives as recommended by the Malaysian Code on Corporate Governance to determine the remuneration of Directors so as to ensure that the Company attracts and retains the Directors needed to run the Company successfully.	The Company has adopted the objectives as recommended by the Malaysian Code of Corporate Governance to determine the remuneration of Directors so as to ensure that the Company attracts and retains the Directors needed to run the Company successfully.

THE IMPACT OF CORPORATE GOVERNANCE MECHANISM ON PERFORMANCE IN EMERGING MARKET
(EVIDENCE FROM TEHRAN STOCK EXCHANGE (TSE))

Hossein Fakhari , Mazandaran University
Abbas Ali Daryaee, Mazandaran University

Abstract

The presence of corporate governance can result in the improved economical performance of the firms and consequently a desirable economical growth in country. However Most of the researches regarding the relationship between corporate governance and the performance of the firms have been conducted in the industrial countries and the lack of this line of research in the emerging markets is completely observable. So we examine the relationship between corporate governance score and firm performance, and evaluate the relatively understudied governance practices in Iran. Also we construct a corporate governance score (CGS) in the firms listed on the Tehran stock exchange. Weak investor protection environment makes Iran a good setting to study how corporate governance practices affect firm value. Using a panel data of firms listed on the Tehran stock exchange from 2004 through 2007, we find that ownership and company-specific characteristics has a significant effect on corporate governance score and subsequent corporate performance. This study recommends that policy makers increase their awareness of the Importance of ownership structure to generate better corporate governance, since managers in weak investor protection environments could differentiate their firms adopting corporate policies to improve their governance structure, and also our measure of governance practices gives investors a quantitative tool to better assess Iranian firms

.*Introduction*

Both accountants and financial economists and financial management have devoted considerable attention to the impact of governance structures. The accounting literature documents that these factors have a substantial impact on earnings management, while the finance literature shows that they likewise affect financial performance. In this paper we examine how governance structure influences firm performance. Although most of the researches regarding the relationship between corporate governance and the performance of the firms have been conducted in the industrial countries and the lack of this line of research in the emerging markets is completely observable. Given the recent importance of corporate governance in academic research and policy, which recently republished the first edition of corporate governance in Iran. we ask a very straightforward question: Do companies in emerging markets that practice better corporate governance receives better performance? That is, do investors care, via valuations, if a firm practices better governance? We are far from being the first to examine this question. Indeed, there is a large literature that has examined this question. For example, Mitton (2004), Brow et al, (2006), Teen & Lei (2007), Cornett et al (2008) , Siregar & utama (2008), Premuroso & Bhattacharya(2007), Epps & Cereola (2007), Garay & González (2008), among others, have examined this question in various emerging markets. This literature has generally found that better governance is indeed linked with higher market valuations and better performance.

However, a review of the former studies shows that the findings do not match with each other, as Black et al. (2006) in their research stated that: " The used criteria in calculating the rating of corporate governance is an important issue to be kept in mind, different indexes of corporate governance can lead to different results". For researchers, different criteria of corporate governance can be another reason for the disparity of previous studies. So we know relatively little about the potential impact that the adoption of corporate governance practices may have on company value and performance in Iran. Measuring this effect are important for the firms because the successor failure of implementing good corporate governance practices may be greater if the market rewards those companies that adopt them. In the case of the US, the empirical evidence shows either no effect or an economically small effect. Black (2001) argues that perhaps these weak results in the US arise because the variation in firm governance is small. Given that the minimum quality of corporate governance, which is set by law and by norms, is very high in that country. On the other hand, inter firm governance variation is found to be much larger in Iran. Although in this research investigate only the effect norm and law on corporate governance .This should not comes a surprise, as a country with weaker laws and norms offers a wider range for governance differences between firms.

Consistent with past research, our paper is similar to Black (2001) and Garay & González (2008), who tested the relation between corporate governance and firm value in Russia and Venezuela as transition economies characterized by weak investor protection. Both papers have a small sample

and Russia, like Iran, is also a country that scores low in terms of investor protection and exhibits a high inter firm variation in corporate governance practices. The evidence reported in this paper is important not only for Iran but also for other emerging markets in the process of attempting to improve their corporate governance practices. The evidence we show here adds to the growing literature worldwide that indicates that firms can differentiate themselves by adopting better corporate governance practices and policies. That is, even in a weak investor protection environment, firms can increase their market value by adopting good corporate governance measures. In general we present the data and conduct our econometric analysis testing the relation between TQ, MB, ROA, and our Gove-Score., we find a positive and strong relation between our index of corporate governance and MTB, TQ and ROA for firms in Iran.
